EMPIRICAL BAYES RULES FOR SELECTING
THE BEST BINOMIAL POPULATION*

Abstract

Consider k populations $\pi_i, i = 1, \ldots, k$, where an observation from $\pi_i$ has binomial distribution with parameters $N$ and $p_i$ (unknown). Let $p[k] = \max_{1 \leq j \leq k} p_j$. A population $\pi_i$ with $p_i = p[k]$ is called a best population. We are interested in selecting the best population. Let $p = (p_1, \ldots, p_k)$ and let $i$ denote the index of the selected population. Under the loss function $l(p, i) = p[k] - p_i$, this statistical selection problem is studied via empirical Bayes approach.

Some selection rules based on monotone empirical Bayes estimators of the binomial parameters are proposed. First, it is shown that, under the squared error loss, the Bayes risks of the proposed monotone empirical Bayes estimators converge to the related minimum Bayes risks with rates of convergence at least of order $O(n^{-1})$, where $n$ is the number of accumulated past experiences at hand. Further, for the selection problem, the rates of convergence of the proposed selection rules are shown to be at least of order $O(\exp(-cn))$ for some $c > 0$.

Abbreviated Title: Empirical Bayes Selection Rules

AMS 1980 Subject Classification: 62F07, 62C12

Key Words and Phrases: Bayes rule, empirical Bayes rule, monotone estimation, monotone selection rule, Asymptotically optimal, rate of convergence

EMPIRICAL BAYES RULES FOR SELECTING
THE BEST BINOMIAL POPULATION

1. Introduction

In many situations, an experimenter is often confronted with choosing a model which is the best in some sense among those under study. For example, consider \( k \) different competing drugs for a certain ailment. We would like to select the best among them in the sense that it has the highest probability of success (cure of the ailment). This kind of binomial model occurs in many fields, such as medicine, engineering, and sociology. The problem of selecting a binomial model associated with the largest probability of success was first considered by Sobel and Huyett (1957) and Gupta and Sobel (1960). The former used the indifference zone formulation and the latter studied the subset selection approach; see Gupta and Huang (1976) and Gupta, Huang and Huang (1976), and Gupta and McDonald (1986) for further variations in goals and procedures for this problem.

Now, consider a situation in which one will be repeatedly dealing with the same selection problem independently. This will be the case with an on-going testing with drugs, for example. In such instances, it is reasonable to formulate the component problem in the sequence as a Bayes decision problem with respect to an unknown prior distribution on the parameter space, and then, use the accumulated observations to improve the decision rule at each
stage. This is the empirical Bayes approach of Robbins (see Robbins (1956, 1964 and 1983)). Many such empirical Bayes rules have been shown to be asymptotically optimal in the sense that the risk for the nth decision problem converges to the minimum Bayes risk which would have been obtained if the prior distribution was known and the Bayes rule with respect to this prior distribution was used.

Empirical Bayes rules have been derived for subset selection goals by Deely (1965). Recently, Gupta and Hsiao (1983) and Gupta and Leu (1983) have studied empirical Bayes rules for selecting good populations with respect to a standard or a control, with the underlying distributions being uniformly distributed. Gupta and Liang (1984) studied empirical Bayes rules for selecting binomial populations better than a standard or a control.

In this paper, we obtain empirical Bayes procedures for selecting the best among k different binomial populations. These rules are based on monotone empirical Bayes estimators of the binomial success probabilities. First, it is shown that, under the squared error loss, the Bayes risks of the proposed monotone empirical Bayes estimators converge to the related minimum Bayes risks with rates of convergence at least of order $O(n^{-1})$. Further, for the selection problem, the rates of convergence of the proposed selection rules are shown to
be at least of order \( O(\exp(-cn)) \) for some \( c > 0 \).

2. **Formulation of the Empirical Bayes Approach**

Consider \( k \) binomial populations \( \pi_i, i = 1, \ldots, k \), each consisting of \( N \) trials. For each \( i, i = 1, \ldots, k \), let \( p_i \) be the probability of success for each trial in \( \pi_i \), and let \( X_i \) denote the number of successes among the associated \( N \) trials. Then, \( X_i | p_i \) is binomially distributed with probability function \( f_i(x \mid p_i) = \binom{N}{x_i} p_i^x_i (1 - p_i)^{N-x_i}, \ x_i = 0, 1, \ldots, N. \) Let \( f(x \mid p) = \prod_{i=1}^k f_i(x_i \mid p_i) \) where \( x = (x_1, \ldots, x_k) \) and \( p = (p_1, \ldots, p_k) \). For each \( p \), let \( p_{(1)} \leq \ldots \leq p_{(k)} \) be the ordered parameters of \( p_1, \ldots, p_k \). It is assumed that the exact matching between the ordered and the unordered parameters is unknown. Any population \( \pi_i \) with \( p_i = p_{(k)} \) is considered as the best population. Our goal is to derive empirical Bayes rules to select the best population.

Let \( \Omega = \{ p \mid p = (p_1, \ldots, p_k), p_i \in (0, 1), i = 1, \ldots, k \} \) be the \( k \) parameter space and \( G(p) = \prod_{i=1}^k G_i(p_i) \) be the prior distribution over \( \Omega \). Let \( A = \{ i \mid i = 1, \ldots, k \} \) be the action space. When action \( i \) is taken, it means that population \( \pi_i \) is selected as the best population. For the parameter \( p \) and action \( i \), the loss function \( \ell(p, i) \) is defined as:

\[
(2.1) \quad \ell(p, i) = p_{(k)} - p_i,
\]

the difference between the best and the selected population.
Let $\mathcal{X} = \prod_{i=1}^{k} \{0, 1, \ldots, N\}$ be the sample space. A selection rule $d = (d_1, \ldots, d_k)$ is a mapping from $\mathcal{X}$ to $[0,1]^k$ such that for each observation $\xi = (x_1, \ldots, x_k)$, the function $d(\xi) = (d_1(\xi), \ldots, d_k(\xi))$ satisfies that $0 \leq d_i(\xi) \leq 1$, $i = 1, \ldots, k$, and $\sum_{i=1}^{k} d_i(\xi) = 1$. Note that $d_i(\xi)$, $i = 1, \ldots, k$, is the probability of selecting population $\pi_i$ as the best population when $\xi$ is observed.

Let $\mathcal{D} = \{d | d : \mathcal{X} \to [0,1]^k, \text{ being measurable} \}$ be the set of all selection rules. For each $d \in \mathcal{D}$, let $r(G,d)$ denote the associated Bayes risk. Then, $r(G) = \inf_{d \in \mathcal{D}} r(G,d)$ is the minimum Bayes risk.

From (2.1), the Bayes risk associated with selection rule $d$ is:

$$r(G,d) = \int \sum_{\Omega} \ell(p, d(\xi)) f(\xi | p) dG(p)$$

$$= C - \sum_{\xi \in \mathcal{X}} \left[ \sum_{i=1}^{k} d_i(\xi) \pi_i(x_i) \right] f(\xi),$$

(2.2)

where $f(\xi) = \prod_{i=1}^{k} f_i(x_i)$, $\pi_i(x) = \frac{W_i(x)}{f_i(x)}$, $f_i(x) = \int f_i(x | p) dG_i(p)$, $W_i(x) = \int pf_i(x | p) dG_i(p)$

$$C = \sum_{\xi \in \mathcal{X}} \int_{\Omega} \mathcal{G}(p | \xi) f(\xi), \text{ being a constant},$$

and $\mathcal{G}(p | \xi)$ is the posterior distribution of $p$ given $\xi$. 

For each \( x \in X \), let

\[
A(x) = \{i|\mathcal{P}_i(x_i) = \max_{1 \leq j \leq k} \mathcal{P}_j(x_j)\}.
\]

Thus, a randomized Bayes rule is

\[
d_G = (d_{1G}, \ldots, d_{kG}),
\]

where

\[
d_{iG}(x) = \begin{cases} 
|A(x)|^{-1}, & \text{if } i \in A(x); \\
0, & \text{otherwise};
\end{cases}
\]

and \(|A|\) denotes the size of the set \( A \).

When the prior distribution \( G \) is unknown, it is impossible to apply the Bayes rules. In this case, we use the empirical Bayes approach. Note that, for each \( i \), \( \mathcal{P}_i(x_i) \) is the posterior mean of the binomial probability \( p_i \) given that \( X_i = x_i \) is observed. Due to the surprising quirk that \( \mathcal{P}_i(x_i) \) can not be consistently estimated in the usual empirical Bayes sense (see Robbins (1964), Samuel (1963) and Vardeman (1978)), we use below an idea of Robbins in setting up the empirical Bayes framework for our selection problem.

For each \( i, i = 1, \ldots, k \), at stage \( j \), consider \( N+1 \) trials from \( \pi_i \). Let \( X_{ij} \) and \( Y_{ij} \) respectively, stand for the number of successes in the first \( N \) trials and the last trial. Let \( P_{ij} \) stand for the probability of success for each of the \( N+1 \) trials. \( P_{ij} \) has distribution \( G_i \). Conditional on \( P_{ij} = p_{ij} \), \( X_{ij}|P_{ij} \sim B(N,p_{ij}) \), \( Y_{ij}|P_{ij} \sim B(1,p_{ij}) \), and \( X_{ij}|P_{ij} \) and \( Y_{ij}|P_{ij} \) are independent. Let \( Z_j = ((X_{1j}, Y_{1j}), \ldots, (X_{kj}, Y_{kj})) \) denote the observations at the \( j \)th stage, \( j = 1, \ldots, n \). We also let \( X_{n+1} = x = (X_1, \ldots, X_k) \) denote the present observations.
Consider an empirical Bayes selection rule $d_n(x; Z_1, \ldots, Z_n) = (d_{1n}(x; Z_1, \ldots, Z_n), \ldots, d_{kn}(x; Z_1, \ldots, Z_n))$. Let $r(G, d_n)$ be the Bayes risk associated with the selection rule $d_n(x; Z_1, \ldots, Z_n)$. Then,

$$r(G, d_n) = \sum_{x \in X} \mathbb{E} \int_{\Omega} \ell(p, d_n(x; Z_1, \ldots, Z_n)) f(x|p) dG(p),$$

where the expectation is taken with respect to $(Z_1, \ldots, Z_n)$. For simplicity, $d_n(x; Z_1, \ldots, Z_n)$ will be denoted by $d_n(x)$.

**Definition 2.1.** A sequence of selection rules $(d_n)_{n=1}^{\infty}$ is said to be asymptotically optimal relative to the prior distribution $G$ if $r(G, d_n) \to r(G)$ as $n \to \infty$.

From (2.4), a natural empirical Bayes selection rule can be defined as follows:

For each $i = 1, \ldots, k$, and $n = 1, 2, \ldots$, let $\mathcal{P}_{in}(x) \equiv \mathcal{P}_{in}(x; (X_{i1}, Y_{i1}), \ldots, (X_{in}, Y_{in}))$ be an estimator of $\mathcal{P}_i(x)$. Let $A_n(x) = (i|\mathcal{P}_{in}(x_i) = \max_{1 \leq j \leq k} \mathcal{P}_{jn}(x_j))$, and define $d_n(x) = (d_{1n}(x), \ldots, d_{kn}(x))$ where

$$d_{in}(x) = \begin{cases} \left|A_n(x)\right|^{-1} & \text{if } i \in A_n(x); \\ 0 & \text{otherwise.} \end{cases}$$

If $\mathcal{P}_{in}(x) \rightarrow \mathcal{P}_i(x)$ for all $x = 0, 1, \ldots, N$ and $i = 1, \ldots, k$ (where "\(\rightarrow\)" means convergence in probability), then, by the boundedness of the loss function $\ell(p, i)$ and Corollary 2 of Robbins (1964), it follows that $r(G, d_n) \to r(G)$ as $n \to \infty$. Thus, the sequence of selection rules $(d_n)_{n=1}^{\infty}$ defined in (2.6) is asymptotically optimal. Hence, our task is only to
find the sequence of estimators \( \{ \hat{y}_{in}(x) \} \) possessing the above mentioned convergence property.

3. **The Proposed Empirical Bayes Selection Rules**

Before we go further to construct empirical Bayes estimators \( \{ \hat{y}_{in}(x) \} \), we first investigate some property related to the Bayes rule \( d_G \) defined in (2.4).

**Definition 3.1.** A selection rule \( d = (d_1, \ldots, d_k) \) is said to be monotone if for each \( i = 1, \ldots, k \), \( d_i(x) \) is increasing in \( x_i \) while all other variables \( x_j \) are fixed, and decreasing in \( x_j \) for each \( j \neq i \) while all other variables are fixed.

Note that \( \hat{y}_i(x) \) is the Bayes estimator of the binomial parameter \( p_i \) under the squared error loss given that \( X_i = x \) is observed. It is also easy to see that \( \hat{y}_i(x) \) is increasing in \( x \) for \( x = 0, 1, \ldots, N \).

**Definition 3.2.** An estimator \( \hat{y}(\cdot) \) is called a monotone estimator if \( \hat{y}(x) \) is an increasing function of \( x \).

By the monotone property of the Bayes estimators \( \hat{y}_i(x) \), \( i = 1, \ldots, k \), one can see that the Bayes selection rule \( d_G \) is a monotone selection rule.

Under the squared error loss, the problem of estimating the binomial parameter \( p_i \) is a monotone estimation problem. By Theorem 8.7 of Berger (1980), for a monotone estimation problem, the class of monotone decision rules form an essentially complete class. With this consideration, it is reasonable to require that the concerned estimators \( \{ \hat{y}_{in}(x) \} \) possess the above monotone property.
In the literature, Robbins (1956) and Vardeman (1978), among others, proposed some estimators for \( \Phi_i(x) \). Those estimators are consistent in that they converge to \( \Phi_i(x) \) in probability. However, they do not possess the monotone property. We now propose some monotone estimators.

For each \( i = 1, \ldots, k, \ n = 1, 2, \ldots, \) and \( x = 0, 1, \ldots, N, \) define

\[
(3.1) \quad f_{in}(x) = \frac{1}{n} \sum_{j=1}^{n} \mathbb{I}_i(x)(X_{ij}) + n^{-1};
\]

\[
(3.2) \quad \hat{W}_{in}(x) = \frac{1}{n} \sum_{j=1}^{n} Y_{ij} \mathbb{I}_i(x)(X_{ij}) + n^{-1};
\]

where \( \mathbb{I}_A(\cdot) \) denotes the indicator function of the set \( A \). Also, let \( V_{ij} = X_{ij} + Y_{ij} \) for each \( i = 1, \ldots, k \) and \( j = 1, 2, \ldots \).

Define

\[
(3.3) \quad \hat{W}_{in}(x) = \left\lfloor \frac{X + 1}{n(N + 1)} \sum_{j=1}^{n} \mathbb{I}_i(x)(V_{ij}) \right\rfloor \wedge \left\lfloor \frac{1}{n} \sum_{j=1}^{n} \mathbb{I}_i(x)(X_{ij}) \right\rfloor + n^{-1},
\]

where \( \wedge \) denotes the minimum of \( a, b \). Let

\[
(3.4) \quad \Psi_{in}(x) = \hat{W}_{in}(x)/f_{in}(x);
\]

\[
(3.5) \quad \hat{\Psi}_{in}(x) = \hat{W}_{in}(x)/f_{in}(x);
\]

and, for each \( 0 \leq x \leq N, \) define

\[
(3.6) \quad \Psi_{in}^{*}(x) = \max_{0 \leq s \leq x} \min_{s \leq t \leq N} \left\{ \sum_{y=s}^{t} \Psi_{in}(y)/(t-s+1) \right\};
\]

\[
(3.7) \quad \hat{\Psi}_{in}^{*}(x) = \max_{0 \leq s \leq x} \min_{s \leq t \leq N} \left\{ \sum_{y=s}^{t} \hat{\Psi}_{in}(y)/(t-s+1) \right\}.
\]
Note that by (3.5) and (3.7), both \( \hat{y}_i^*(x) \) and \( \check{y}_i^*(x) \) are increasing in \( x \). We propose \( \hat{y}_i^*(x) \) (or \( \check{y}_i^*(x) \)) as an estimator of \( p_i(x) \). Let

(3.8) \[
A_n^*(x) = \{ i | \hat{y}_i^*(x_i) = \max_{1 \leq j \leq k} \hat{y}_j^*(x_j) \} ;
\]

(3.9) \[
\tilde{A}_n^*(x) = \{ i | \check{y}_i^*(x_i) = \max_{1 \leq j \leq k} \check{y}_j^*(x_j) \} .
\]

Two selection rules \( d_n^* = (d_{1n}^*, \ldots, d_{kn}^*) \) and \( \tilde{d}_n^* = (\tilde{d}_{1n}^*, \ldots, \tilde{d}_{kn}^*) \) analogous to the Bayes selection rule \( d_G \) are proposed as follows:

For each \( i = 1, \ldots, k \), let

(3.10) \[
d_{1n}^*(x_i) = \begin{cases} 
|A_n^*(x_i)|^{-1} & \text{if } i \in A_n^*(x) ; \\
0 & \text{otherwise} ;
\end{cases}
\]

and

(3.11) \[
\tilde{d}_{1n}^*(x_i) = \begin{cases} 
|\tilde{A}_n^*(x_i)|^{-1} & \text{if } i \in \tilde{A}_n^*(x) ; \\
0 & \text{otherwise} .
\end{cases}
\]

Due to the monotone property of the estimators \( \hat{y}_i^*(x_i) ; i = 1, \ldots, k \) and \( \check{y}_i^*(x_i) ; i = 1, \ldots, k \), one can see that \( d_n^* \) and \( \tilde{d}_n^* \) are both monotone selection rules.

4. **Asymptotic Optimality of the Monotone Estimators**

In this section, we study the asymptotic optimality property of the estimators \( \hat{y}_i^*(x) \) and \( \check{y}_i^*(x) \). Under the squared error loss, \( \varphi_1(x) \) is the Bayes estimator of \( p_1 \). The associated Bayes risk is

(4.1) \[
R_1(G_1) = E[(P_1 - \varphi_1(X_1))^2] .
\]
Let \( \hat{Y}_r(\cdot) \) be any estimator of \( p_r \) with the associated Bayes risk \( R_i(G_i, \hat{Y}_r) \). Then,

\[
(4.2) \quad R_i(G_i, \hat{Y}_r) - R_i(G_i) = \mathbb{E}[(\hat{Y}_r(X_1) - Y_1)^2].
\]

Let \( \{\hat{Y}_{in}(x; (X_{i1}, Y_{i1}), \ldots, (X_{in}, Y_{in})) = \hat{Y}_{in}(x) \} \) be a sequence of empirical Bayes estimators based on \( (x; (X_{i1}, Y_{i1}), \ldots, (X_{in}, Y_{in})) \).

**Definition 4.1.** A sequence of empirical Bayes estimators \( \{\hat{Y}_{in}^*\}_{n=1}^\infty \) is said to be asymptotically optimal at least of order \( \alpha_n \) relative to the prior \( G_i \) if \( R_i(G_i, \hat{Y}_{in}^*) - R_i(G_i) \leq O(\alpha_n) \) as \( n \to \infty \) where \( \{\alpha_n\} \) is a sequence of positive values satisfying \( \lim_{n \to \infty} \alpha_n = 0 \).

**Theorem 4.1.** Let \( \{\hat{Y}_{in}^*\} \) and \( \{\tilde{\hat{Y}}_{in}^*\} \) be the sequences of empirical Bayes estimators defined in (3.6) and (3.7), respectively. Then,

\[
R_i(G_i, \hat{Y}_{in}^*) - R_i(G_i) \leq O(n^{-1})
\]

and

\[
R_i(G_i, \tilde{\hat{Y}}_{in}^*) - R_i(G_i) \leq O(n^{-1}).
\]

The following lemmas are useful in presenting a concise proof of Theorem 4.1.

**Lemma 4.1.** Let \( Z \) be a random variable and \( z \) be a real number such that \( -\infty \leq a \leq Z, z \leq b \leq \infty \). Then, for any \( s > 0 \),

\[
\mathbb{E}[|Z-z|^s] = \int_{-\infty}^a z - a s^{s-1} P(Z < t) dt + \int_{a}^{b} s^{s-1} P(Z > t) dt + \int_{b}^{\infty} s^{s-1} P(Z > t) dt,
\]

provided that the expectation exists.

**Proof:** Straightforward computation.
Lemma 4.2. For the estimators $\hat{\varphi}_i$ and $\hat{\varphi}_i^*$ defined in (3.4) and (3.6), respectively, we have

a) $\hat{\varphi}_i^*(0) \leq \hat{\varphi}_i(0), \hat{\varphi}_i^*(N) \geq \hat{\varphi}_i(N)$.

b) For $1 \leq x \leq N-1$,

$\hat{\varphi}_i^*(x) > \hat{\varphi}_i(x)$ iff there is some $y < x$

such that $\hat{\varphi}_i(y) > \hat{\varphi}_i(x)$;

$\hat{\varphi}_i^*(x) < \hat{\varphi}_i(x)$ iff there is some $y > x$

such that $\hat{\varphi}_i(y) < \hat{\varphi}_i(x)$.

c) For $0 \leq x \leq N$,

$$P(\hat{\varphi}_i^*(x) - \hat{\varphi}_i(x) > t) \leq \sum_{y=0}^{x} P(\hat{\varphi}_i(y) - \hat{\varphi}_i(y) > t);$$

$$P(\hat{\varphi}_i^*(x) - \hat{\varphi}_i(x) < -t) \leq \sum_{y=x}^{N} P(\hat{\varphi}_i(y) - \hat{\varphi}_i(y) < -t).$$

Proof: Parts a) and b) are straightforward from (3.6). Part c) is a result of parts a) and b) and an application of Bonferroni's inequality.

Remark 4.1. Lemma 4.2 is also true if $\hat{\varphi}_i$ and $\hat{\varphi}_i^*$ are replaced by $\tilde{\varphi}_i$ and $\tilde{\varphi}_i^*$, respectively.

Lemma 4.3. For $0 < t < 1 - \hat{\varphi}_i(x)$ and $0 \leq y \leq x$,

a) $P(\hat{\varphi}_i(y) - \hat{\varphi}_i(y) > t) \leq \exp(-2n\alpha_1^2(t,y,n,i))$; and

b) $P(\tilde{\varphi}_i(y) - \hat{\varphi}_i(y) > t) \leq \exp(-\frac{n}{2}\alpha_1^2(t,y,n,i))$,

if $t > b(n,y,i)$, where $b(n,y,i) = (1-\hat{\varphi}_i(y))(n^{-1}/f_i(y) + n^{-1})$ and $\alpha_1(t,y,n,i) = t(f_i(y) + n^{-1}) - n^{-1}(1-\hat{\varphi}_i(y))$.

For $0 < t < \hat{\varphi}_i(x)$ and $x \leq y \leq N$,

c) $P(\hat{\varphi}_i(y) - \hat{\varphi}_i(y) < -t) \leq \exp(-2n\alpha_2^2(t,y,n,i))$; and
d) \( P(\hat{\varphi}_1(n) - \varphi_1(y) < -t) \leq 2 \exp\left(-\frac{n}{2} a_2^2(t, y, n, i)\right) \), where \( a_2(t, y, n, i) = -t (f_1(y) + n^{-1}) - n^{-1}(1 - \varphi_1(y)) \).

Proof: Here we prove part a) only. Other parts follow by a similar reasoning.

For \( 0 < t < 1 - \varphi_1(x) \) and \( 0 \leq y \leq x \), by (3.1), (3.2), (3.4) and the fact that \( \varphi_1(y) = \bar{W}_1(x)/f_1(x) \), following a straightforward computation, one can obtain

\[
P(\varphi_1(n) - \varphi_1(y) > t) = P(W_1(y) - (\varphi_1(y) + t) f_1(n) > 0)
\]

(4.3)

\[
= P\left\{ \frac{1}{n} \sum_{j=1}^{n} I_{\{y\}}(X_{ij})[Y_{ij} - \varphi_1(y) - t] + t f_1(y) > a_1(t, y, n, i) \right\}.
\]

Note that \( I_{\{y\}}(X_{ij})[Y_{ij} - \varphi_1(y) - t], j = 1, 2, \ldots, n \) are i.i.d., \( -\varphi_1(y) - t \leq I_{\{y\}}(X_{ij})[Y_{ij} - \varphi_1(y) - t] \leq 1 - \varphi_1(y) - t \) for all \( j \), and \( E[I_{\{y\}}(X_{ij})[Y_{ij} - \varphi_1(y) - t]] = -t f_1(y) \). Also, \( a_1(t, y, n, i) > 0 \) iff \( t > b(n, y, i) \). Hence, by (4.3) and Theorem 2 of Hoeffding (1963), \( P(\varphi_1(n) - \varphi_1(y) > t) \leq \exp\left(-2n a_1^2(t, y, n, i)\right) \) if \( t > b(n, y, i) \).

Remark 4.2. Lemma 4.3 is still true if the strict inequality \( < \) (\( > \) ) is replaced by \( \leq \) (\( \geq \)).

Lemma 4.4. For \( 0 \leq y \leq x \),

a) \[ \int_0^{1-\varphi_1(x)} \text{tP}(\varphi_1(n) - \varphi_1(y) > t) \, dt \leq O(n^{-1}); \text{and} \]

b) \[ \int_0^{1-\varphi_1(x)} \text{tP}(\tilde{\varphi}_1(n) - \varphi_1(y) > t) \, dt \leq O(n^{-1}). \]
For $x \leq y \leq N$,
\[
\int_0^{\Phi_i(x)} tP(\Phi_{in}(x) - \Phi_1(y) < -t)dt \leq O(n^{-1}); \text{ and}
\]
\[
\int_0^{\Phi_i(x)} tP(\Phi_{in}(y) - \Phi_1(y) < -t)dt \leq O(n^{-1}).
\]

Proof: We prove part a) only.

Case 1. As $b(n,y,i) \geq 1 - \Phi_i(x)$, then
\[
1 - \Phi_i(x) \leq \int_0^{b(n,y,i)} t dt
\]
\[
= b^2(n,y,i)/2
\]
\[
= O(n^{-2}).
\]

Case 2. As $b(n,y,i) < 1 - \Phi_i(x)$, then, by Lemma 4.3.a) and a direct computation,
\[
1 - \Phi_i(x) \leq \int_0^{b(n,y,i)} t dt + \int_{b(n,y,i)}^{1 - \Phi_i(x)} tP(\Phi_{in}(y) - \Phi_1(y) > t)dt
\]
\[
\leq 0(n^{-2}) + 0(n^{-1})
\]
\[
= O(n^{-1}).
\]
Proof of Theorem 4.1.

By (4.2),

\[ 0 \leq R_1(G_1, \varphi^*_1, y) - R_1(G_1) \]

\[ = \frac{E[(\varphi^*_1(x) - \varphi_1(x))^2]}{N} \]

\[ = \sum_{x=0}^{N} E[(\varphi^*_1(x) - \varphi_1(x))^2 | X = x] f_1(x). \]

By Lemmas 4.1 - 4.3 and the fact that \( 0 \leq \varphi^*_1(x), \varphi_1(x) \leq 1 \), one can obtain that

\[ E[(\varphi^*_1(x) - \varphi_1(x))^2 | X = x] \]

\[ = \int_0^{1-\varphi_1(x)} 2tP(\varphi^*_1(x) - \varphi_1(x) < -t) dt \]

\[ + \int_{1-\varphi_1(x)}^{1} 2tP(\varphi^*_1(x) - \varphi_1(x) > t) dt \]

(4.5)

\[ \leq \sum_{x=0}^{N} \int_0^{1-\varphi_1(x)} 2tP(\varphi_1(y) - \varphi_1(y) < -t) dt \]

\[ + \sum_{y=0}^{x} \int_{1-\varphi_1(x)}^{1} 2tP(\varphi_1(y) - \varphi_1(y) > t) dt. \]

Then, by Lemma 4.4, (4.4), (4.5) and the fact that \( N \) is a finite number, therefore, \( R_1(G_1, \varphi^*_1, y) - R_1(G_1) \leq O(n^{-1}). \)

The similar claim for \( \varphi^*_1 \) is established on the same lines.
5. Asymptotic Optimality of the Selection Rules

Let \( \{d_n^\infty\}_n \) be a sequence of empirical Bayes selection rules relative to the prior distribution \( G \). Since the Bayes rule \( d_G \) achieves the minimum Bayes risk \( r(G) \), \( r(G, d_n) - r(G) \geq 0 \) for all \( n = 1, 2, \ldots \). Thus, the nonnegative difference \( r(G, d_n) - r(G) \) is used as a measure of the optimality of the sequence of empirical Bayes rules \( \{d_n\}_n \).

**Definition 5.1.** The sequence of empirical Bayes rules \( \{d_n\}_n \) is said to be asymptotically optimal at least of order \( \beta_n \) relative to the prior \( G \) if \( r(G, d_n) - r(G) \leq O(\beta_n) \) as \( n \to \infty \) where \( \{\beta_n\} \) is a sequence of positive numbers such that \( \lim_{n \to \infty} \beta_n = 0 \).

For each \( \chi \in \mathcal{X} \), let \( A(\chi) \) be that defined in (2.3) and let \( B(\chi) = \{1, \ldots, k\} - A(\chi) \). Thus, for each \( \chi \in \mathcal{X} \), \( \psi_i(x_i) > \psi_j(x_j) \) for \( i \in A(\chi) \) and \( j \in B(\chi) \). Let \( \varepsilon = \min_{\chi \in \mathcal{X}} \{P(\psi_i(x_i) - \psi_j(x_j)| i \in A(\chi), j \in B(\chi)) \} \). Hence, \( \varepsilon > 0 \) since \( \mathcal{X} \) is a finite space.

Then,

\[
0 \leq r(G, d_n^*) - r(G)
\]

\[
\leq \sum_{\chi \in \mathcal{X}} \sum_{i \in A(\chi)} \sum_{j \in B(\chi)} P(\psi_{in}^*(x_i) \leq \psi_{jn}^*(x_j)).
\]

(5.1)
Now, for each $x, i \in A(x), j \in B(x)$,

$$P(\Psi^*_{in}(x_i) \leq \Psi^*_{jn}(x_j))$$

$$= P(\Psi^*_{in}(x_i) - \Psi^*_{jn}(x_j) \leq \Psi^*_{jn}(x_i) - \Psi^*_{jn}(x_j) \leq \Psi^*_{jn}(x_j) - \Psi^*_{jn}(x_i) \leq -\varepsilon)$$

$$\leq P(\Psi^*_{jn}(x_i) - \Psi^*_{jn}(x_j) \leq -\varepsilon/2) + P(\Psi^*_{jn}(x_i) - \Psi^*_{jn}(x_j) \geq \varepsilon/2).$$

In (5.2), the first inequality is due to the definition of $\varepsilon$.

From (2.3), it suffices to consider the asymptotic behavior of
the probabilities $P(\Psi^*_{jn}(x_j) - \Psi^*_{jn}(x_j) \geq \varepsilon/2)$
and $P(\Psi^*_{jn}(x_i) - \Psi^*_{jn}(x_i) \leq -\varepsilon/2)$.

Let $c_1 = \min_{1 \leq i \leq k} \min_{0 \leq y \leq N} (\varepsilon^2 f_i^2(y)/2)$. Then $c_1 > 0$. From the
definitions of $\varepsilon$ and $b(n, y, i)$, we see that, for
sufficiently large $n$, $\varepsilon > 2 \max_{1 \leq i \leq k} \max_{0 \leq y \leq N} \{b(n, y, i)\}$. Therefore, by
Lemma 4.2 (c) and remark 4.2, for $n$ large enough,

$$P(\Psi^*_{jn}(x_i) - \Psi^*_{jn}(x_i) \geq \varepsilon/2)$$

$$\leq \sum_{y=0}^{x_i} P(\Psi^*_{jn}(y) - \Psi^*_{jn}(y) \geq \varepsilon/2)$$

$$\leq \sum_{y=0}^{x_i} \exp(-2na_1^2(\varepsilon/2, y, n, i))$$

$$\leq O(\exp(-c_1 n)).$$

The last step of (5.3) follows from the fact that
$\exp(-2na_1^2(t, y, n, i)) \leq O(\exp(-c_1 n))$ for all $0 \leq y \leq N$ and $1 \leq i \leq k$,
which is established easily by a straightforward computation
and definitions of $a_1(\varepsilon/2, y, n, i)$ and $c_1$. 
Similarly, one can prove that

$$P(P_{in}^*(x_i) - P_1(x_i) \leq -\varepsilon/2) \leq \sum_{y=x_i}^{N} \exp(-2n\alpha_2^2(\varepsilon/2, y, n, i)) \leq O(\exp(-c_1n)).$$

(5.4)

Therefore, from (5.1) to (5.4), and the finiteness of the space $\mathcal{X}$, we have

$$0 \leq r(G, d_n^*) - r(G) \leq O(\exp(-c_1n)).$$

Similarly, for the sequence of empirical Bayes selection rules $(\tilde{d}_n^*)_{n=1}^\infty$, we can prove that

$$0 \leq r(G, \tilde{d}_n^*) - r(G) \leq O(\exp(-c_2n))$$

for some $c_2 > 0$.

We now state these results as a theorem.

**Theorem 5.1.** Let $(d_n^*)_{n=1}^\infty$ and $(\tilde{d}_n^*)_{n=1}^\infty$ be the sequences of empirical Bayes selection rules defined in (3.10) and (3.11), respectively. Then,

$$r(G, d_n^*) - r(G) \leq O(\exp(-c_1n)),$$

and

$$r(G, \tilde{d}_n^*) - r(G) \leq O(\exp(-c_2n))$$

for some $c_i > 0$, $i = 1, 2$.

Bayes rule; Empirical Bayes Rules, Monotone Estimation, Monotone Selection Rules, Asymptotically Optimal, Rate of Convergence.

Consider k populations \( \pi_i, i = 1, \ldots, k \), where an observation from \( \pi_i \) has binomial distribution with parameters \( N \) and \( p_i \) (unknown). Let \( p[k] = \max_{1 \leq j \leq k} p_j \). A population \( \pi_i \) with \( p_i = p[k] \) is called a best population. We are interested in selecting the best population. Let \( p = (p_1, \ldots, p_k) \) and let \( i \) denote the index of the selected population.
Under the loss function $\ell(p, i) = p_{[k]} - p_i$, this statistical selection problem is studied via empirical Bayes approach.

Some selection rules based on monotone empirical Bayes estimators of the binomial parameters are proposed. First, it is shown that, under the squared error loss, the Bayes risks of the proposed monotone empirical Bayes estimators converge to the related minimum Bayes risks with rates of convergence at least of order $O(n^{-1})$, where $n$ is the number of accumulated past experiences at hand. Further, for the selection problem, the rates of convergence of the proposed selection rules are shown to be at least of order $O(\exp(-cn))$ for some $c > 0$.
