Abstract. Stochastic Volterra equations are studied where the coefficients $F(t,s,x)$ are random and adapted to $\mathcal{F}_{s\wedge t}$ rather than the customary $\mathcal{F}_{s\wedge t}$. Such a hypothesis, which is natural in several applications, leads to stochastic integrals with anticipating integrands. We interpret these as Skorohod integrals, which generalize Itô’s integrals to the case where the integrand anticipates the future of the Wiener integrator. The solutions are nevertheless adapted processes and even semimartingales if the coefficients are smooth enough.

Key words and phrases Stochastic Volterra equations, Anticipating stochastic calculus, Skorohod integral.
1 Introduction

Let $\Omega$ denote the space $C(\mathbb{R}_+, \mathbb{R}^k)$ equipped with the topology of uniform convergence on compact sets, $\mathcal{F}$ the Borel $\sigma$-field on $\Omega$, $P$ standard Wiener measure, and let $\{W_t(\omega) = \omega(t), t \geq 0\}$. For any $t \geq 0$, we define $\mathcal{F}_t = \sigma\{\omega(s), s \leq t\} \vee \mathcal{N}$, where $\mathcal{N}$ denotes the class of the elements in $\mathcal{F}$ which have zero $P$-measure. Our aim in this paper is to study equations of the following form, whose solution $\{X_t\}$ should be an $\mathbb{R}^d$-valued and $\mathcal{F}_t$ adapted process:

\begin{equation}
X_t = X_0 + \int_0^t F(t,s,X_s) \, ds + \int_0^t G_i(H_t,t,s,X_s) \, dW_s^i,
\end{equation}

where we use here and everywhere below the Einstein convention of summation upon repeated indices (i.e. (1.1) should be read with a “$\sum_{i=1}^k$” added in front of the second integral), and $\{H_t\}$ is an $\mathbb{R}^p$-valued and $\mathcal{F}_t$-adapted process, $F(t,s,x)$, maps $\Omega \times \{s,t; 0 \leq s \leq t\} \times \mathbb{R}^d$ into $\mathbb{R}^d$ and $F(t,\cdot,\cdot)$ is $\mathcal{F}_t$ adapted, and $G_i(h,t,s,x), \ldots, G_k(h,t,s,x)$ map $\Omega \times \mathbb{R}^p \times \{s,t; 0 \leq s \leq t\} \times \mathbb{R}^d$ into $\mathbb{R}^d$ and $G_i(\cdot,\cdot,\cdot), \ldots, G_k(\cdot,\cdot,\cdot)$ are $\mathcal{F}_s$ adapted.

A special case of equation (1.1) is a more standard Volterra equation:

\begin{equation}
X_t = X_0 + \int_0^t J(t,s)X_s \, ds + \int_0^t K_i(H_t,t,s)X_s \, dW_s^i,
\end{equation}

where $J(\cdot,\cdot)$ and $K_1(\cdot,\cdot,\cdot), \ldots, K_k(\cdot,\cdot,\cdot)$ are $d \times d$ matrices. The novelty here is that $G_1(h,t,s,x), \ldots, G_k(h,t,s,x)$ are $\mathcal{F}_t$-adapted, and not $\mathcal{F}_s$-adapted, i.e. the integrands in the stochastic integrals are anticipating.

Note that $G_1(H_t,t,s,X_s), \ldots, G_k(H_t,t,s,X_s)$ anticipate the increments of $\{W_t\}$ between $s$ and $t$ in a special and restrictive way, namely through $H_t$. We shall explain below the reason for this restriction.

Volterra equations with kernels which anticipate in the way described above arise in applications (in particular in Finance theory, see [4]) and as such were the motivation for this work.

Clearly the problem in studying the above class of equations is that the integrands in the stochastic integrals are not adapted, and therefore one cannot use as usual the Itô integral to interpret the equation. Our approach is to use the Skorohod integral [19] to interpret the stochastic integrals in (1.1) and (1.2). Recent progress in interpreting the Skorohod integral (see [10], [11] and [15]) have made this possible. We explain our interpretation of the equation in section 2. Note that recently there has been other work concerning stochastic differential equations where the solution itself is anticipating (which is not the case here). In [18], the Skorohod integral was used to solve a one-dimensional linear equation with an anticipating initial condition. In [12], [13], and [14], another kind of generalized stochastic integral, which generalizes the Stratonovich integral, was used to solve stochastic differential equations with an anticipating initial condition, or with boundary conditions (instead of the usual initial condition).

This article builds on previous work concerning stochastic Volterra equations. Equations where the kernel is adapted to $\mathcal{F}_s$ were studied among others in [2], [6], [16] and [17]; Berger and Mizez considered linear stochastic Volterra equations with anticipating...
integrands in [3]. Our results differ from theirs since the stochastic integral is not the same, also the discussion in [3] uses in an essential way the linearity of the coefficients. In [16], one of us commented that such equations can also be studied using an “enlargement of filtration” approach, but the technique used in the present paper yields much better (and perhaps more “natural”) results.

The paper is organized as follows. Section 2 contains a presentation of some results concerning the Skorohod integral, which will be used later, together with the precise interpretation of equation (1.1). The existence and uniqueness of a solution to equation (1.1) is proved in two steps in sections 3 and 4. In section 5, we establish, under additional assumptions, the existence of an a.s. continuous modification of the solution process. This allows us to deduce a weaker existence and uniqueness result, under local Lipschitz conditions. Under still stronger regularity assumptions on the coefficients, we show in section 6 that the unique continuous solution is a semimartingale.

Let us point out the fact that the reason for restricting ourselves to a Wiener driving process (versus a more general semimartingale) is the fact that the Skorohod integral and the derivations which we will be using below are only defined on Wiener space.

The following notation is used throughout the paper: $c(\alpha, \beta)$ stands for a constant which depends only on $\alpha$ and $\beta$, and whose value may vary from one occurrence to another.

2. The Skorohod integral

Most of this section is a review of some basic notions and a few results from Nualart-Pardoux [10]. Let again $\Omega = C(\mathbb{R}_+; \mathbb{R}^k)$, $\mathcal{F}$ be its Borel field and $P$ denote Wiener measure on $(\Omega, \mathcal{F})$. $W_t(\omega) = \omega(t)$. Let $\mathcal{F}_t^\omega = \sigma(W_s; 0 \leq s \leq t)$ and $\mathcal{F}_t = \mathcal{F}_t^\omega \vee \mathcal{N}$, where $\mathcal{N}$ denotes the class of $P$-null sets of $\mathcal{F}$. For $h \in L^2(\mathbb{R}_+; \mathbb{R}^k)$, we denote by $W(h)$ the Wiener integral

$$W(h) = \int_0^\infty (h(t), dW_t)$$

Let $\mathcal{S}$ denote the dense subset of $L^2(\Omega, \mathcal{F}, P)$ consisting of those classes of random variables of the form:

$$(2.1) \quad F = f(W(h_1), \ldots, W(h_n))$$

where $n \in \mathbb{N}$, $f \in C^0_c(\mathbb{R}^n)$, $h_1, \ldots, h_n \in L^2(\mathbb{R}_+; \mathbb{R}^k)$. If $F$ has the form (2.1), we define its derivative in the direction $i$ as the process $\{D^i_tF, t \geq 0\}$ defined by:

$$D^i_tF = \sum_{k=1}^n \frac{\partial f}{\partial x_k}(W(h_1), \ldots, W(h_n))h_k^i(t)$$

$DF$ will stand for the $k$-dimensional process $\{D_tF = (D^1_tF, \ldots, D^k_tF); t \geq 0\}$.

**Proposition 2.1.** For $i = 1, \ldots, k$, $D^i$ is an unbounded closable operator from $L^2(\Omega)$ into $L^2(\mathbb{R}_+ \times \mathbb{R}_+)$.

We identify $D^i$ with its closed extension, and denote by $D^{1,2}_i$ its domain. $D^{1,2} = \bigcap_{i=1}^k D^{1,2}_i$ is the domain of $D : L^2(\Omega) \rightarrow L^2(\mathbb{R}_+ \times \mathbb{R}_+; \mathbb{R}^k)$. □

Note that $D^{1,2}_i$ (resp. $D^{1,2}$) is the closure of $\mathcal{S}$ with respect to the norm

$$\|F\|_{i,1,2} = \|F\|_2 + \|D^i_F\|_{L^2(\mathbb{R}_+)}$$
(resp. with respect to the norm :

\[ \|F\|_{1,2} = \|F\|_2 + \sum_{i=1}^{k} \|D^i F\|_{L^2(\mathbb{R}_+)} \]

\( D^i \) is a local operator, in the sense that : \( D^i F = 0 \) d\( F \times dt \) a.e on \( \{ F = 0 \} \times \mathbb{R}_+ \). We denote by \( D^{1,2}_{i,loc} \) the set of measurable \( F^i \)-s which are such that there exists a sequence \( \{(\Omega_n, F_n); n \in \mathbb{N}\} \subset \mathcal{F} \times D^{1,2}_i \) with the two properties :

(i) \( \Omega_n \uparrow \Omega \) a.s., \( n \to \infty \)

(ii) \( F_n|\Omega_n = F|\Omega_n, n \in \mathbb{N} \)

For \( F \in D^{1,2}_{i,loc} \), we define without ambiguity \( D^i F \) by : \( D^i F = D^i_F \) on \( \Omega_n \times \mathbb{R}_+ \), \( \forall n \in \mathbb{N} \). \( D^{1,2}_{i,loc} \) is defined similarly.

For \( i = 1, \ldots, k \), we define \( \delta_i \) the Skorohod integral with respect to \( \{W_t\} \) as the adjoint of \( D^i \), i.e. \( Dom\delta_i \) is the set of \( u \in L^2(\Omega \times \mathbb{R}_+) \) which are such that there exists a constant \( c \) with :

\[ |E \int_0^\infty D^i_F u_t \, dt| \leq c\|F\|_2, \forall F \in \mathcal{S}. \]

If \( u \in Dom\delta_i \), \( \delta_i(u) \) is defined as the unique element of \( L^2(\Omega) \) which satisfies :

\[ E(\delta_i(u)F) = E \int_0^\infty D^i_F u_t \, dt, \forall F \in \mathcal{S}. \]

Let \( \mathcal{L}^{1,2}_i = L^2(\mathbb{R}_+; D^{1,2}_i) \). We have that \( \mathcal{L}^{1,2}_i \subset Dom\delta_i \), and for \( u \in \mathcal{L}^{1,2}_i \),

\[ E[\delta_i(u^2)] = E \int_0^\infty u^2_t \, dt + E \int_0^\infty \int_0^\infty D^i_s u_t D^i_t u_s \, dsdt. \]

(2.2)

Note that \( \{u \in L^2(\Omega \times \mathbb{R}_+); u \) is \( \mathcal{F}_t \) progressively measurable \( \} \subset Dom\delta_i \), and for such a \( u \), \( \delta_i(u) \) coincides with the usual Itô integral. Note that when \( u \) is progressively measurable, \( D_s u_t = 0 \) for \( s > t \), so that (2.2) is consistent with the formula in the adapted case.

**Remark 2.2.** From (2.2), the \( L^2(\Omega) \) norm of a Skorohod integral can be estimated in terms of the \( L^2(\Omega) \) norm of its integrand plus a norm of its derivative. This means that an \( L^2(\Omega) \) estimate of the last term in (1.1) introduces the derivative of the solution \( X \). This creates a crucial difficulty if we try to apply standard techniques to study existence and uniqueness of (1.1). That is the motivation for letting \( G_i \) anticipate the increments \( \{W_r - W_s; s \leq r \leq t\} \) only through the process \( \{H_i\} \).

Note that if \( u \in L^{1,2}_{loc}(\mathbb{R}_+; D^{1,2}_i) \), then for any \( T > 0, u1_{[0,T]} \in \mathcal{L}^{1,2}_i \) and we can define:

\[ \int_0^T u_t \, dW_t^i = \delta_i(u1_{[0,T]}). \]
The Skorohod integral is a local operation on $L^2_{loc}(\mathbb{R}^+; D_i^{1,2})$ in the sense that if $u, v \in L^2_{loc}(\mathbb{R}^+; D_i^{1,2})$, $\int_0^t u_s \, dW^i_s = \int_0^t v_s \, dW^i_s$ a.s. on $\{\omega; u_s(\omega) = v_s(\omega) \text{ for almost all } s \leq t\}$.

Let $\mathcal{L}_{i,loc}^1$ denote the set of measurable processes $u$ which are such that for any $T > 0$ there exists a sequence $\{(\Omega^T_n, u^T_n); n \in \mathbb{N}\} \subset \mathcal{F} \times \mathcal{L}_i^{1,2}$ such that :

\[(i) \quad \Omega^T_n \uparrow \Omega \text{ a.s., as } n \to \infty \]

\[(ii) \quad u = u^T_n \, dP \times dt \text{ a.e. on } \Omega^T_n \times [0, T], n \in \mathbb{N}. \]

For $u \in \mathcal{L}_{i,loc}^1$, we can define its Skorohod integral with respect to $W^i_t$ by :

\[
\int_0^t u_s \, dW^i_s = \int_0^t u^T_{n,s} \, dW^i_s \text{ on } \Omega^T_n \times [0, T].
\]

Finally, $\mathcal{L}^{1,2} = \bigcap_{i=1}^k \mathcal{L}_i^{1,2}$, and $\mathcal{L}_{i,loc}^1$ is defined similarly as $\mathcal{L}_{i,loc}^1$.

We now introduce the particular class of integrands which we shall use below. Let $u : \mathbb{R}^+ \times \Omega \times \mathbb{R}^p \to \mathbb{R}$ satisfy :

\[(i) \quad \forall x \in \mathbb{R}^p, (t, \omega) \to u(t, \omega, x) \text{ is } \mathcal{F}_t \text{ progressively measurable.} \]

\[(ii) \quad \forall (t, \omega) \in \mathbb{R}^+ \times \Omega, u(t, \omega, \cdot) \in C^1(\mathbb{R}^p) \]

\[(iii) \quad \text{For some increasing function } \varphi : \mathbb{R}^+ \to \mathbb{R}^+,
\]

\[|u(t, \omega, x)| + |u'(t, \omega, x)| \leq \varphi(|x|), \forall (t, \omega, x) \in \mathbb{R}^+ \times \Omega \times \mathbb{R}^p \]

where $u'(t, x)$ stands for the gradient $\frac{\partial u}{\partial x}(t, x)$.

Let $\theta$ be a $p$-dimensional random vector such that :

\[(iv) \quad \theta^j \in D_i^{1,2} \cap L^\infty(\Omega); j = 1, \ldots, p \]

Let us fix $T > 0$, and consider :

\[I^i(x) = \int_0^T u(t, x) \, dW^i_t \]

Define moreover $v_t = u(t, \theta)$. Under conditions $(i), \ldots, (iv)$, the following holds :
Proposition 2.3. The random field \( \{ I^i(x); x \in \mathbb{R}^p \} \) defined above possesses an a.s. continuous modification, so that we can define the r.v. \( I^i(\theta) \). Moreover \( v \in Dom\delta_i \), and the following holds:

\[
\int_0^T v_t \, dW^i_t = I^i(\theta) - \int_0^T u'(t, \theta) D^i_t \theta \, dt
\]

\( \square \)

Proposition 2.3 is proved in Nualart-Pardoux [10], under slightly different conditions. We shall need below a localized version of that result.

We replace condition (iv) by:

(iv') \( \theta^j \in D^{1,2}_{i,loc}; \ j = 1, \ldots, p \)

Under conditions (i),(ii),(iii) and (iv'), \( v \in (Dom\delta_i)_{loc} \), in the sense that there exists a sequence \( \{(\Omega_n, v_n); n \in \mathbb{N}\} \subset \mathcal{F} \times Dom\delta_i \) such that \( \Omega_n \uparrow \Omega \) a.s. and \( v_n|\Omega_n = v|\Omega_n \). Indeed, let \( \{(\Omega'_n, \theta_n)\} \) be a localizing sequence for \( \theta \) in \( (D^{1,2}_i)_{loc} \), and \( \{\psi_n; n \in \mathbb{N}\} \subset C_c^\infty(\mathbb{R}^p; \mathbb{R}^p) \) satisfy \( \psi_n(x) = x \) whenever \( |x| \leq n \). Define:

\[
v_n(t) = u(t, \psi_n(\theta_n))
\]

\[
\Omega_n = \Omega'_n \cap \{ |\theta| \leq n \}
\]

Then \( \{(\Omega_n, v_n); n \in \mathbb{N}\} \) satisfies the above conditions.

It is then natural to define the Skorohod integral \( \int_0^T v_t \, dW^i_t \) again by formula (2.3), and the latter coincides with \( \int_0^T v_n(t) \, dW^i_t \) on \( \Omega_n \). Note that our definition of \( \int_0^T v_t \, dW^i_t \) does not depend on the localizing sequence of \( v \) in \( Dom\delta_i \), provided that sequence is of the form \( \{u(\cdot, \theta_n)\} \) with \( \theta_n \) satisfying (iv).
3. Statement of the problem. Interpretation of equation (1.1)

Our aim is to study the equation:

\[(3.1) \quad X_t = X_0 + \int_0^t F(t,s,X_s) \, ds + \int_0^t G_i(H_t;t,s,X_s) \, dW^i_s,\]

where we use here and henceforth the convention of summation upon repeated indices. We define \(D = \{(t,s) \in \mathbb{R}_+^2; \quad 0 \leq s \leq t\}\). The coefficients \(F\) and \(G\) are given as follows: \(F: \Omega \times D \times \mathbb{R}^d \to \mathbb{R}^d\) is measurable and for each \((s,x) \in \mathbb{R}_+ \times \mathbb{R}^d\), \(F(\cdot,s,x)\) is \(\mathcal{F}_s\)-progressively measurable on \(\Omega \times [s, +\infty)\). For \(i = 1, \ldots, k\), \(G_i: \Omega \times \mathbb{R}^p \times D \times \mathbb{R}^d \to \mathbb{R}^d\) is measurable, for each \((h,t,x), G_i(h;t,\cdot,x)\) is \(\mathcal{F}_s\)-progressively measurable on \(\Omega \times [0,t]\), and for each \((\omega,t,s,x), G_i(\cdot;t,s,x)\) is of class \(C^1\).

\(\{H_t\}\) is a given progressively measurable \(p\)-dimensional process. It will follow from these hypotheses that the solution \(\{X_t\}\) will be progressively measurable. Therefore, for each \(t\), the process

\[\{G_i(H_t;t,s,X_s); \quad s \in [0,t]\}\]

is of the form \(v_s = u(s,\theta)\) with \(u(s,h) = G_i(h;t,s,X_s)\) and \(\theta = H_t\). We shall impose below conditions on \(G\), \(\{H_t\}\) and the solution \(\{X_t\}\) so as to satisfy the requirements (i), (ii), (iii) and (iv') of the last section. Therefore the stochastic integrals in (3.1) will be interpreted according to (2.3), i.e. :

\[(3.2) \quad \int_0^t G_i(H_t;t,s,X_s) \, dW^i_s = \int_0^t G_i(h;t,s,X_s) \, dW^i_s|_{h=H_t} - \int_0^t G'_i(H_t;t,s,X_s)D^i_sH_t \, ds\]

In other words, we can rewrite (3.1) as :

\[(3.3) \quad X_t = X_0 + \int_0^t \bar{F}(t,s,X_s) \, ds + \int_0^t G_i(h;t,s,X_s) \, dW^i_s|_{h=H_t}\]

where

\[\bar{F}(t,s,x) = F(t,s,x) - G'_i(H_t;t,s,x)D^i_sH_t\]

and the stochastic integrals are now the usual Itô integrals.
4. Existence and Uniqueness under strong hypotheses.
Let us formulate a set of further hypotheses (thoes stated in 3 are assumed to hold throughout the paper), under which we will establish a first result of the existence and uniqueness of a solution of equations of the form (1.1).

Let $B$ be an open bounded subset of $\mathbb{R}^p$, $K > 0$ and $q > p$ s.t. :

(H.1) $X_0 \in L^q(\Omega, \mathcal{F}_0, P; \mathbb{R}^d)$

(H.2) $P(H_t \in B, \forall t \geq 0) = 1$

(H.3) $H \in (L^{1,2})^p; |D_s H_t| \leq K$ a.s., $0 \leq s \leq t$

(H.4) $|F(t, s, x)| + \sum_{i=1}^{k} |G_i(h; t, s, x)| + \sum_{i=1}^{k} |G'_i(h; t, s, x)| \leq K(1 + |x|)$

for any $0 \leq s \leq t$, $h \in B$, $x \in \mathbb{R}^d$ and a.s.

\[
|F(t, s, x) - F(t, s, y)| + \sum_{i=1}^{k} |G_i(h; t, s, x) - G_i(h; t, s, y)| + \sum_{i=1}^{k} |G'_i(h; t, s, x) - G'_i(h; t, s, y)| \leq K|x - y|
\]

for any $0 \leq s \leq t$, $h \in B$, $x, y \in \mathbb{R}^d$ and a.s.

Note that from now on $q$ will be a fixed real number s.t. $q > p$ and (H.1) holds. $L^q_{prog}(\Omega \times (0, t))$ will stand for the space $L^q(\Omega \times (0, t), \mathcal{P}_t, P \times \lambda)$, where $\mathcal{P}_t$ denotes the $\sigma$-algebra of progressively measurable subsets of $\Omega \times (0, t)$ and $\lambda$ denotes the Lebesgue measure on $(0, t)$.

**Lemma 4.1.** Let $X \in \bigcap_{t>0} L^q_{prog}(\Omega \times (0, t))$, where $q > p$, and suppose that (H.4) is in force. Then for any $t > 0$ and $i \in \{1, \ldots, k\}$, the random field :

\[
\{ \int_0^t G_i(h; t, s, X_s) \, dW_s^i; h \in B \}
\]

possesses an a.s. continuous modification.

**Proof:** Using Burkholder-Gundy's and Hölder's inequalities together with (H.4), we obtain :

\[
E(|\int_0^t G_i(h; t, s, X_s) \, dW_s^i - \int_0^t G_i(k; t, s, X_s) \, dW_s^i|^q)
\]

\[
\leq c(t, q)E \int_0^t |G_i(h; t, s, X_s) - G_i(k; t, s, X_s)|^q \, ds
\]

\[
\leq c(t, q)K^q|h - k|^q E \int_0^t (1 + |X_s|)^q \, ds
\]
The result now follows from the multidimensional generalization of Kolmogorov's Lemma (see e.g. Sznitman [20]).

We can and will from now on assume that for $t$ fixed, the random field

$$ \{ \int_0^t G_i(h; t, s, X_s) \, dW_s^i; \, h \in B \} $$

is a.s. continuous in $h$, provided $X \in L^q_{pro}(\Omega \times (0, t))$.

For $X \in \bigcap_{t>0} L^q_{pro}(\Omega \times (0, t))$, define

$$ I_t(X, h) = \sum_{i=1}^k \int_0^t G_i(h; t, s, X_s) \, dW_s^i, \quad h \in \mathbb{R}^p, \quad t > 0 $$

$$ J_t(X) = \int_0^t \tilde{F}(t, s, X_s) \, ds + I_t(X, H_t). $$

**Lemma 4.2.** For any $t > 0$, $\exists c(q, t)$ s.t.:

$$ E(|J_t(X)|^q) \leq c(q, t)(1 + E \int_0^t |X_s|^q \, ds) $$

**Proof:**

$$ |\int_0^t \tilde{F}(t, s, X_s) \, ds|^q \leq c(q, t) \int_0^t |\tilde{F}(t, s, X_s)|^q \, ds $$

$$ \leq c(q, t)(1 + \int_0^t |X_s|^q \, ds) $$

where we have used (H.2), (H.3) and (H.4).

$$ |I_t(X, H_t)| \leq \sup_{h \in B} |I_t(X, h)|. $$

It is easy to show, using in particular (H.4) and Lebesgue's dominated convergence theorem, that the mapping:

$$ h \rightarrow I_t(X, h) $$

from $\mathbb{R}^p$ into $L^q(\Omega)$ is differentiable, and that:

$$ \frac{\partial I_t(X, h)}{\partial h_j} = \int_0^t \frac{\partial G_i}{\partial h_j}(h; t, s, X_s) \, dW_s^i. $$

Since $q > p$, we can infer from Sobolev's embedding theorem (see e.g. Adams [1], Theorem 5.4.1.c):

$$ E \left( \sup_{h \in B} |I_t(X, h)|^q \right) \leq c(q) E \int_B (|I_t(X, h)|^q + \sum_{j=1}^p |\frac{\partial I_t(X, h)}{\partial h_j}|^q) \, dh $$
It then follows from the Burkholder-Gundy inequality that:

\[
E \left( \sup_{h \in B} |I_t(X, h)|^q \right) \\
\leq c(q, t) E \int_B \int_0^t (|G_i(h; t, s, X_s)|^q + \sum_{j=1}^p \left| \frac{\partial G_i}{\partial h_j}(h; t, s, X_s) \right|^q) \, ds \, dh \\
\leq c(q, t) \left( \int_B dh \right)(1 + E \int_0^t |X_s|^q \, ds)
\]

where we have used (H.4) and the relative compactness of $B$. □

A similar argument, but using (H.5) instead of (H.4), yields:

**Lemma 4.3.** For any $t > 0$, $\exists c(q, t)$ s.t.

\[
E(|J_t(X) - J_t(Y)|^q) \leq c(q, t) E \int_0^t |X_s - Y_s|^q \, ds
\]

If moreover $\tau$ is a stopping time,

\[
E(|J_{t \wedge \tau}(X) - J_{t \wedge \tau}(Y)|^q) \leq c(q, t) E \int_0^{t \wedge \tau} |X_s - Y_s|^q \, ds.
\]

□

We are now in a position to prove the main result of this section.

**Theorem 4.4.** Under conditions (H.1), (H.2), (H.3), (H.4) and (H.5), there exists a unique element $X \in \bigcap_{t > 0} L^q_{pro}(\Omega \times (0, t))$, which solves equation (3.1). Moreover, if $\tau$ is a stopping time, uniqueness holds on the random interval $[0, \tau]$.

**Proof:** Equation (3.1) can be rewritten as:

\[
(4.1) \quad X_t = X_0 + J_t(X), \, t \geq 0
\]

**Uniqueness:** Let $X, Y \in \bigcap_{t > 0} L^q_{pro}(\Omega \times (0, t))$ and $\tau$ be a stopping time, such that:

\[
X_t = X_0 + J_t(X), \, 0 \leq t \leq \tau \\
Y_t = X_0 + J_t(Y), \, 0 \leq t \leq \tau \\
X_{t \wedge \tau} - Y_{t \wedge \tau} = J_{t \wedge \tau}(X) - J_{t \wedge \tau}(Y)
\]

From Lemma 2.3,

\[
E(|X_{t \wedge \tau} - Y_{t \wedge \tau}|^q) \leq c(q, t) E \int_0^{t \wedge \tau} |X_s - Y_s|^q \, ds \\
\leq c(q, t) E \int_0^t |X_{s \wedge \tau} - Y_{s \wedge \tau}|^q \, ds
\]

...
The result now follows from Gronwall’s Lemma.

**Existence:** Lemmas 2.2 and 2.3 allow us to mimic Itô’s classical proof. Let us define a sequence \( \{X^n_t, t \geq 0; n \in \mathbb{N}\} \) as follows:

\[
X^0_t = X_0, \quad t \geq 0
\]

\[
X^{n+1}_t = X_0 + J_t(X^n), \quad t \geq 0; \quad n \in \mathbb{N}
\]

(4.2)

Using Lemma 2.3, we show inductively that

\[
X^n \in \bigcap_{t>0} L^q_{\text{prog}}(\Omega \times (0,t)); \quad n \in \mathbb{N}
\]

It then follows from Lemma 2.3:

\[
E(|X^{n+1}_t - X^n_t|^q) \leq c(q,t) \int_0^t E(|X^s_t - X^{s-1}_s|^q) \, ds
\]

A classical argument then shows that: \( E(|X^{n+1}_t - X^n_t|^q) \leq E(|X_0|^q) \frac{C^{n+1}_t n^{n+1}}{(n+1)!} \) which implies that \( X^n \) is a Cauchy sequence in \( L^q_{\text{prog}}(\Omega \times (0,t)) \); \( \forall t > 0 \). Then there exists \( X \) s.t. \( X^n \rightarrow X \)

in \( \bigcap_{t>0} L^q_{\text{prog}}(\Omega \times (0,t)) \), and using again Lemma 2.3, we can pass to the limit in (4.2), yielding that \( X \) solves (4.1). □

5. **An existence and uniqueness result under weaker assumptions**

Our aim is this section is to "localize" the result of section 4. We formulate a new set of weaker hypotheses.

(H.1') \( X_0 \) is \( \mathcal{F}_0 \) measurable.

(H.2') \( H \in (L^{1,2}_{\text{loc}})^p \), \( \{H_t\} \) is a progressively measurable process which can be localized in \((L^{1,2})^p\) by a progressively measurable sequence.

We assume that there exists an increasing progressively measurable process \( \{U_t, t \geq 0\} \) with values in \( \mathbb{R}_+ \), such that:

\[
|H_t| + \sum_{i=1}^k |D^i_s H_t| \leq U_t \text{ a.s., } 0 \leq s \leq t
\]

Finally we suppose that for any \( N > 0 \), there exists an increasing progressively measurable process \( \{V_t^N, t \geq 0\} \) with values in \( \mathbb{R}_+ \), such that:

\[
|F(t, s, x)| + \sum_{i=1}^p |G_i(h; t, s, x)| + \sum_{i=1}^p |G'_i(h; t, s, x)|
\]

\[
\leq V^N_t (1 + |x|) \quad \forall |h| \leq N, \quad 0 \leq s \leq t, \quad x \in \mathbb{R}^d.
\]

\[
|F(t, s, x) - F(t, s, y)| + \sum_{i=1}^p |G_i(h; t, s, x) - G_i(h; t, s, y)| +
\]

\[
\sum_{i=1}^p |G'_i(h; t, s, x) - G'_i(h; t, s, y)| \leq V^N_t |x - y|
\]

\( \forall |h| \leq N, \quad 0 \leq s \leq t, \quad x, y \in \mathbb{R}^d. \)

Let again \( q \) be a fixed real number, with \( q > p \). We have:
Theorem 5.1. Equation (3.1) has a unique solution in the class of progressively measurable processes which satisfy:

\[ X \in \bigcap_{t>0} L^q(0, t) \quad \text{a.s.} \]

Proof: a) Let us first see how equation (3.1) makes sense if \( X \in \bigcap_{t>0} L^q(0, t) \) a.s. That is, we have to show that for \( t > 0 \) fixed,

\[ \left\{ \int_0^t G_i(h; t, s, X_s) \, dW^i_s; \ h \in \mathbb{R}^p \right\} \]

is a well defined random field which possesses an a.s. continuous modification. For that sake, we define:

\[ \tau_n = \inf \{ t; \int_0^t |X_s|^q \, ds \geq n \text{ or } V_t^N \geq n \} \]

The argument of Lemma 4.1 can be used to show that:

\[ h \rightarrow \int_0^{t^{\wedge} \tau_n} G_i(h; t, s, X_s) \, dW^i_s \]

possesses an a.s. continuous modification on \( \{|h| \leq N\} \). Since this is true for any \( n \) and \( N \), and \( \bigcup_n \{ \tau_n \geq t \} = \Omega \) a.s., the result follows.

b) Existence: We want to show existence on an arbitrary interval \([0, T]\) (\( T \) will be fixed below). Let \( \{H^n; n \in \mathbb{N}\} \) denote a progressively measurable localizing sequence for \( H \) in \( \mathbb{L}^{1,2} \) on \([0, T]\). Since from (H.3') \( \sup_{t \leq T} |H_t| \) is a.s. finite, we can and do assume w.l.o.g. that:

\[ |H^n_t(\omega)| \leq n, \quad \forall (t, \omega) \in [0, T] \times \Omega. \]

Note that \( H_t(\omega) = H^n_t(\omega) \) a.s. on \( \Omega^T_n \), \( \forall t \in [0, T]\), where \( \mathbb{P}_n \rightarrow \Omega \) a.s. as \( n \rightarrow \infty \).

We moreover define:

\[ X^n_0 = X_0 1_{\{|X_0| \leq n\}} \]

\[ S_n = \inf \{ t; \sup_{s \leq t} |D_s H^n_t| \vee V^n_t \geq n \} \]

We consider the equation:

\[ X^n_t = X^n_0 + \int_0^t \tilde{F}^n(t, s, X^n_s) \, ds + \int_0^t G^n_i(h; t, s, X^n_s) \, dW^i_s |_{h=H^n_t} \]  

where:

\[ \tilde{F}^n(t, s, x) = 1_{[0, s_n]}(s) [F(t, s, x) - G^n_i(H^n_t; t, x) D^n_i H^n_t] \]

\[ G^n_i(h; t, s, x) = 1_{[0, s_n]}(s) G_i(h; t, s, x). \]

It is not hard to see that Theorem 4.4 applies to equation (5.1).

Define:

\[ \bar{S}_n(\omega) = \left\{ \begin{array}{ll} S_n(\omega) \wedge \inf \{ t \leq T; \int_0^t |H_s(\omega) - H^n_s(\omega)| \, ds > 0 \}, & \text{if } |X_0(\omega)| \leq n; \\ 0, & \text{otherwise}. \end{array} \right. \]
$\tilde{S}_n$ is a stopping time, and it follows from the uniqueness part of Theorem 4.4 that, if $m > n$:

$$X_t^m = X_t^n \text{ on } [0, \tilde{S}_n], \text{ a.s.}$$

Since moreover $\{\tilde{S}_n = T\} \uparrow \Omega$ a.s., we can define the process $\{X_t\}$ on $[0, T]$ by:

$$X_t = X_t^n \text{ on } [0, \tilde{S}_n], \forall n \in \mathbb{N}.$$  

Clearly, $X \in \bigcap L^q(0, T)$ a.s. and solves (3.1) on $[0, T]$. Since $T$ is arbitrary, the existence is proved.

c) Uniqueness: It suffices to prove uniqueness on an arbitrary interval $[0, T]$. Let $\{\tilde{X}_t, t \in [0, T]\}$ be a progressively measurable process s.t. $\tilde{X} \in L^q(0, T)$ a.s. and $\tilde{X}$ solves (3.1). It suffices to show that $\tilde{X}$ coincides with the solution we have just constructed. Let:

$$\tilde{S}_n(\omega) = \tilde{S}(\omega) \wedge \inf\{t \leq T; \int_0^t |\tilde{X}_s(\omega)|^q \, ds \geq n\}$$

$$\tilde{X}_t^n = \tilde{X}_t \wedge \tilde{S}_n$$

$\tilde{X}^n \in L^q(\Omega \times [0, T])$ and it solves equation (5.1) with $S_n$ replaced by $\tilde{S}_n$. Then

$$\tilde{X}_t^n(\omega) = X_t(\omega) \quad dt \times dP \text{ a.e. on } [0, \tilde{S}_n].$$

The result follows from the fact that $\{\tilde{S}_n \geq T\} \uparrow \Omega$ a.s.

Note that the above solution satisfies in fact $X \in \bigcap_{q \geq 1} \bigcap_{t \geq 0} L^q(0, t)$ a.s.
6. Continuity of the solution

We want now to give additional conditions under which the solution of equation (3.1) is an a.s. continuous process.

\( \forall (s, x) \in \mathbb{R}_+ \times \mathbb{R}^d, t \rightarrow F(t, s, x) \) is a.s. continuous on \((s, +\infty)\).

(H.6)

\( \{H_t; t \geq 0\} \) is a.s. continuous.

(H.7)

\( \forall i \in \{1, \ldots, k\}, s \in \mathbb{R}_+, t \rightarrow D^i_s H_t \) is a.s. continuous on \((s, +\infty)\).

(H.8)

\( \forall (s, x) \in \mathbb{R}_+ \times \mathbb{R}^d, i \in \{1, \ldots, k\}, (t, h) \rightarrow G^i_t(h; t, s, x) \) is a.s. continuous on \((s, +\infty) \times \mathbb{R}^p\).

(H.9)

We also suppose that there exist \( \alpha > 0, \lambda > 0 \) s.t.:

\[
\forall N > 0, |h| \leq N, 0 \leq s \leq t \wedge r, x \in \mathbb{R}^d, |t - r| \leq 1,
\]

there exists an increasing process \( \{V^N_t; t \geq 0\} \) such that:

\[
|G^i_t(h; t, s, x) - G^i_t(h; r, s, x)| \leq V^N_t |t - r|^\alpha (1 + |x|).
\]

(H.10)

Theorem 6.1. Under conditions (H.1'), ..., (H.5'), (H.6), ..., (H.10), the unique solution of equation (3.1) (which belongs a.s. to \( \cap_{t \geq 0} \cap_{t > 0} L^p(0, t) \)) has an a.s. continuous modification.

Proof: We need to show only that whenever \( X \in \cap_{t \geq 1} \cap_{t > 0} L^q(0, t) \) a.s., \( \{J_t(X), t \geq 0\} \) has an a.s. continuous modification.

a) We first show that \( t \rightarrow \int_0^t \tilde{F}(t, s, X_s) \, ds \) is a.s. continuous. Note that (H.6), (H.7), (H.8) and (H.9) imply that \( \forall (s, x) \in \mathbb{R}_+ \times \mathbb{R}^d \),

\[
(6.1) \quad t \rightarrow \tilde{F}(t, s, x) \text{ is a.s. continuous on } (s, +\infty).
\]

Moreover, from (H.2'), (H.3'), (H.4') and the fact that \( X \in \cap_{t \geq 1} \cap_{t > 0} L^q(0, t) \) a.s., for any \( T > 0 \), there exists a process \( \{Z^T_s; s \in [0, T]\} \) such that :

\[
(6.2) \quad |\tilde{F}(t, s, X_s)| \leq Z^T_s, \quad 0 \leq s \leq t \leq T \text{ a.s.}
\]

\[
(6.3) \quad \int_0^t Z^T_s \, ds < \infty \text{ a.s.}
\]

Let first \( \{t_n, n \in \mathbb{N}\} \) be a sequence such that \( t_n < t \) for any \( n \) and \( t_n \rightarrow t \) as \( n \rightarrow \infty \).

\[
\int_0^t \tilde{F}(t, s, X_s) \, ds - \int_0^{t_n} \tilde{F}(t_n, s, X_s) \, ds
\]

\[
= \int_{t_n}^t \tilde{F}(t, s, X_s) \, ds + \int_0^{t_n} [\tilde{F}(t, s, X_s)] \, ds - \tilde{F}(t_n, s, X_s) \, ds
\]

14
\[ |\int_{t_n}^{t} \bar{F}(t, s, X_s) \, ds| \leq \int_{t_n}^{t} Z_s^T \, ds \]

and the latter tends a.s. to zero as \( n \to \infty \).

\[ |\int_{0}^{t} [\bar{F}(t, s, X_s) - \bar{F}(t_n, s, X_s)] \, ds| \leq \int_{0}^{t} |\bar{F}(t, s, X_s) - \bar{F}(t_n, s, X_s)| \, ds \]

which tends to zero from (6.1),(6.2),(6.3) and Lebesgue’s dominated convergence theorem. A similar argument gives the same result when \( t_n > t, t_n \to t \).

b) We next show that \( t \to I_t(X, H_t) \) possesses an a.s. continuous modification. This will follow from (H.7) and :

\[ (t, h) \to I_t(X, h) \text{ has an a.s. continuous modification.} \]

By localization, it suffices to prove (6.4) under the assumptions (H.2), \( \ldots \), (H.5), (H.6), \( \ldots \), (H.10), with \( V_t^N(\omega) \) in (H.10) replaced by a constant \( K \), and in case \( X_0 \in \bigcap_{q \geq 1} L^q(\Omega; \mathbb{R}^d) \).

It then suffices to show that under the above hypotheses, there exists \( c, q > 0 \) and \( \beta > p + 1 \) such that

\[ (6.5) \]

\[ E(|I_t(X, h) - I_r(X, k)|^q) \leq c(|t - r|^{\beta} + |h - k|^{\beta}) \]

for any \( h, k \in \mathbb{R}^p; t, r > 0 \). Suppose, to fix the ideas, that \( 0 \leq r \leq t \).

\[ I_t(X, h) - I_r(X, k) = \int_{r}^{t} G_i(h; t, s, X_s) \, dW_s^i \]

\[ + \int_{0}^{r} [G_i(h; t, s, X_s) - G_i(h; r, s, X_s)] \, dW_s^i + \int_{0}^{r} [G_i(h; r, s, X_s) - G_i(k; r, s, X_s)] \, dW_s^i \]

It follows from the Burkholder-Gundy inequality:

\[ E(|\int_{r}^{t} G_i(h; t, s, X_s) \, dW_s^i|^q) \leq c_q \sum_{i=1}^{k} E \left[ \left( \int_{r}^{t} |G_i(h; t, s, X_s)|^2 \, ds \right)^{q/2} \right] \]

\[ \leq c_q (t - r)^{\frac{q-2}{2}} \sum_{i=1}^{k} E \int_{r}^{t} |G_i(h; t, s, X_s)|^q \, ds \]

\[ \leq c_q (t - r)^{\frac{q-2}{2}} \]

From (H.4) for \( G_i^t \), we deduce:

\[ E \left( |\int_{0}^{r} [G_i(h; r, s, X_s) - G_i(k; r, s, X_s)] \, dW_s^i|^q \right) \leq c_q (h - k)^q (1 + E \int_{0}^{r} |X_s|^q \, ds) \]

\[ \leq c_q (h - k)^q \]

From (H.10),

\[ E \left( |\int_{r}^{t} [G_i(h; t, s, X_s) - G_i(h; r, s, X_s)] \, dW_s^i|^q \right) \leq K_{r,q} |t - r|^{\alpha q} (1 + E \int_{0}^{r} |X_s|^q \, ds) \]

\[ \leq c_q |t - r|^{\alpha q} \]

(6.5) now follows from the above estimate, provided we chose \( q \) such that \( \inf \left( \frac{q-2}{2}, \alpha q \right) > q + 1 \).
7. Semimartingale property of the solution

Under the conditions of Theorem 6.1, there exists a unique (in the sense of Theorem 5.1) continuous solution \( \{X_t, t \geq 0\} \) of the equation:

\[
X_t = X_0 + \int_0^t F(t, s, X_s) \, ds + \int_0^t G_i(H_i; t, s, X_s) \, dW_s^i
\]

which we rewrite, with the notations of the above sections, as:

\[
X_t = X_0 + \int_0^t \tilde{F}(t, s, X_s) \, ds + I_t(X, H_t)
\]

We now want to state conditions under which both \( \{\int_0^t \tilde{F}(t, s, X_s); t \geq 0\} \) and \( \{I_t(X, H_t); t \geq 0\} \) are semi-martingales (and then also \( \{X_t; t \geq 0\} \)). In order to avoid some technicalities, we shall state some of the conditions in terms of \( \tilde{F} \) (and not explicitly in terms of \( F, G \) and \( \{H_t\} \)) for simplicity. In any event, our conditions are easy to check for each example.

Let us first treat the term \( \{\int_0^t \tilde{F}(t, s, X_s) \, ds\} \). We shall assume that for any \((s, x) \in \mathbb{R}_+ \times \mathbb{R}^d\), the process \( \{\tilde{F}(t, s, X_s), t \geq s\} \) can be rewritten in the form:

\[
\tilde{F}(t, s, x) = \tilde{F}(s, s, x) + \int_s^t \Gamma(\theta, s, x) \, d\theta + \int_s^t \Lambda_i(\theta, s, x) \, dW^i_\theta
\]

where \( \Gamma, \Lambda_1, \ldots, \Lambda_k \) are measurable mappings from \( \Omega \times D \times \mathbb{R}^d \) into \( \mathbb{R}^d \), and for each \((s, x) \in \mathbb{R}_+ \times \mathbb{R}^d\), \( \Gamma(\cdot, s, x), \Lambda_1(\cdot, s, x), \ldots, \Lambda_k(\cdot, s, x) \) are progressively measurable on \( \Omega \times [s, +\infty) \).

It follows from (H.5') that \( x \to \tilde{F}(s, s, x) \) is continuous for any \((\omega, s)\). We suppose moreover that \( x \to \Gamma(\theta, s, x) \) is continuous for any \((\omega, \theta, s) \in \Omega \times D\), and that for any \( N > 0 \) there exists \( \mathbb{R}_+ \)-valued measurable functions \( c_N \) and \( d_N \) defined on \( \Omega \times D \), which are progressively measurable in \((\theta, \omega)\) on \( \Omega \times [s, +\infty) \) for any fixed \( s \), and such that for some \( q > d \) and any \( 0 \leq s < t, N \in \mathbb{N} \),

\[
(H.11) \quad \int_s^t c_N(\theta, s) \, d\theta < \infty \text{ a.s., } E \int_s^t (d_N(\theta, s))^q \, d\theta < \infty
\]

\[
(H.12) \quad \sup_{|x| \leq N} \left( |\Gamma(\theta, s, x)| + \sum_{i=1}^k |\Lambda_i(\theta, s, x)|^2 \right) \leq c_N(\theta, s)
\]

\[
(H.13) \quad |\Lambda(\theta, s, x) - \Lambda(\theta, s, y)| \leq d_N(\theta, s)|x - y|, \forall x, y \in \mathbb{R}^d \text{ s.t. } |x| \vee |y| \leq N
\]

It then follows that each term in (7.2) is a.s. continuous in \( x \), after a possible choice of another modification (for the stochastic integral terms, we apply the argument in Lemma 4.1). It is then not hard to show that:

\[
\tilde{F}(t, s, X_s) = \tilde{F}(s, s, X_s) + \int_s^t \Gamma(\theta, s, X_s) \, d\theta + \int_s^t \Lambda_i(\theta, s, X_s) \, dW^i_\theta
\]
It follows from (H.12) that we can use Fubini theorems (the one for the stochastic integral terms can be found e.g. in Jacod [5, Theorem 5.44]) to conclude:

$$
\int_0^t \bar{F}(t, s, X_s) \, ds = \int_0^t \bar{F}(s, s, X_s) \, ds + \int_0^t \int_0^\theta \Gamma(\theta, s, X_s) \, d\theta \, ds + \int_0^t \int_0^\theta \Lambda_i(\theta, s, X_s) \, ds \, dW^i_\theta
$$

(7.3)

We have shown:

**Proposition 7.1.** Under conditions (H.1'), (H.2'), (H.3'), (H.4'), (H.5'), (H.11), (H.12) and (H.13), \( \{ \int_0^t \bar{F}(t, s, X_s) \, ds; t \geq 0 \} \) is a semi-martingale whose decomposition is given by (7.3). □

We now consider \( I_t(X, H_t) \). Let us assume that \( \{ H_t \} \) is a semi-martingale of the form:

$$
H_t = H_0 + \int_0^t K_s \, ds + \int_0^t L^i_t \, dW^i_s
$$

(H.14)

where \( H_0 \) is a \( \mathcal{F}_0 \) measurable \( p \)-dimensional random vector, \( \{ K_t, L^1_t, \ldots, L^k_t \} \) are progressively measurable \( p \)-dimensional random processes with:

$$
\int_0^t (|K_s| + \sum_{i=1}^k |L^i_s|^2) \, ds < \infty \text{ a.s.}, \forall t > 0
$$

(H.15)

We suppose moreover that for any \((\omega, s, x), G_i(\cdot; s, x)\) is of class \( C^{2, 1} \) (\( C^2 \) in \( h \) and \( C^1 \) in \( t \)) and moreover for any \( N > 0; h, k \in \mathbb{R}^p \) s.t. \( |h|, |k| \leq N; r, s, t \in \mathbb{R}_+; x \in \mathbb{R}^d; 1 \leq i \leq k \),

$$
\left| \frac{\partial G_i}{\partial h}(h; t, s, x) \right| + \left| \frac{\partial^2 G_i}{\partial h^2}(h; t, s, x) \right| + \left| \frac{\partial G_i}{\partial t}(h; t, s, x) \right| \leq V_{iN}^N(1 + |x|)
$$

(H.16)

$$
\left| \frac{\partial^2 G_i}{\partial h^2}(h; t, s, x) - \frac{\partial^2 G_i}{\partial h^2}(k; t, s, x) \right| + \left| \frac{\partial G_i}{\partial r}(h; t, s, x) - \frac{\partial G_i}{\partial r}(k; r, s, x) \right|
\leq V_{ivr}^N(1 + |x|)(|h - k| + |t - r|),
$$

(H.17)

where again \( \{ V_{iN}^N, t \geq 0 \} \) \( \in \mathbb{N} \) is a collection of increasing and progressively measurable \( \mathbb{R}_+ \) valued processes. Let us now denote by \( \{ I_t(X, h, r) \} \) the collection of processes indexed by \( (h, r) \in \mathbb{R}^p \times \mathbb{R}_+ \):

$$
I_t(X, h, r) = \int_0^t G_i(h; r, s, X_s) \, dW^i_s
$$

Combining the argument of Lemma 4.1 for \( q > p + 1 \) with a localization procedure, we obtain:
Lemma 7.2. For each $t > 0$, $(h, r) \to I_t(X, h, r)$ is a.s. of class $C^{2,1}$, and:

\[
\frac{\partial}{\partial h} I_t(X, h, r) = \int_0^t \frac{\partial G_i}{\partial h}(h; r, s, X_s) \, dW^i_s
\]

\[
\frac{\partial^2}{\partial h^2} I_t(X, h, r) = \int_0^t \frac{\partial^2 G_i}{\partial h^2}(h; r, s, X_s) \, dW^i_s
\]

\[
\frac{\partial}{\partial r} I_t(X, h, r) = \int_0^t \frac{\partial G_i}{\partial r}(h; r, s, X_s) \, dW^i_s,
\]

$I$ and its derivatives being jointly continuous in $(t, h, r)$.\[\square\]

It then follows from an adaptation of Theorem 1.7.1. in Kunita [7] (see the Appendix) that:

Proposition 7.3. Under the above conditions, in particular (H.14), (H.15), (H.16) and (H.17), \( \{I_t(X, H_t, t), t \geq 0\} \) is a semi-martingale whose decomposition is given by:

\[
I_t(X, H_t, t) = \int_0^t G_i(H_s; s, s, X_s) \, dW^i_s
\]

\[
+ \int_0^t \left( \frac{\partial I^i}{\partial r}(X, H_s, s) + \frac{\partial I^i}{\partial h}(X, H_s, s) K_s \right) \, ds
\]

\[
+ \int_0^t \frac{\partial I^i}{\partial h}(X, H_s, s) L_s^i \, dW^i_s + \frac{1}{2} \int_0^t \left( \frac{\partial^2 I^i}{\partial h^2}(X, H_s, s) L_s^i, L_s^i \right) \, ds
\]

\[\square\]

We can now conclude:

Theorem 7.4. Assume that conditions (H.1'), ..., (H.5') and (H.11), ..., (H.17) are in force. Then the unique solution \( \{X_t; t \geq 0\} \) of equations (3.1) is a continuous semi-martingale which takes the form:

\[
X_t = X_0 + \int_0^t \bar{F}(s, s, X_s) \, ds + \int_0^t \int_0^s \Gamma(\theta, s, X_s) \, ds \, d\theta
\]

\[
+ \int_0^t \int_0^s \Lambda_i(\theta, s, X_s) \, dW^i_\theta \]

\[
+ \int_0^t \int_0^s \frac{\partial G_i}{\partial r}(H_s; s, s, H_s) \, dW^i_s \, d\theta + \int_0^t \left( \int_0^s \frac{\partial G_i}{\partial h}(H_s; s, s, X_s) \, dW^i_s \right) K_\theta \, d\theta
\]

\[
+ \int_0^t \left( \int_0^s \frac{\partial G_i}{\partial h}(H_s; s, s, X_s) \, dW^i_s \right) L^i_\theta \, dW^i_\theta
\]

\[
+ \frac{1}{2} \int_0^t \left[ \left( \int_0^s \frac{\partial^2 G_i}{\partial h^2}(H_s; s, s, X_s) \, dW^i_s \right) L^i_\theta, L^i_\theta \right] \, d\theta
\]

\[\square\]

18
Appendix

The aim of this Appendix is to prove the following Itô-Ventzell formula, which generalizes Theorem I.7.1. in Kunita[7]. Szmitman [20] has analogous results for general semi-martingales.

**Theorem.** Let \( \{T_t(h, r); t \geq 0\}_{(h, r) \in \mathbb{R}^p \times R_+} \) be a collection of d-dimensional semi-martingales of the form:

\[
T_t(h, r) = T_0(h, r) \int_0^t U_s(h, r) \, ds + \int_0^t V_s^i(h, r) \, dW^i_s
\]

where \( \{W^1_t, \ldots, W^k_t; t \geq 0\} \) are mutually independent \( \mathcal{F}_t \)-Wiener processes defined on \((\Omega, \mathcal{F}, P), \{U_t(h, r), V_t^1(h, r), \ldots, V_t^k(h, r); t \geq 0\}_{(h, r) \in \mathbb{R}^p \times R_+}\) are progressively measurable processes s.t. \( h \rightarrow (V_t^1(h, r), \ldots, V_t^k(h, r)) \) is of class \( C^1 \), \( \forall (\omega, t, r) \in \Omega \times \mathbb{R}_+^2 \), and:

(HA.1) \( \forall N \in \mathbb{N}, t > 0, \) there exists an \( R_+ \)-valued progressively measurable process \( \{\alpha_s^{t,N}; 0 \leq s \leq t\} \) such that:

\[
\int_0^t \alpha_s^{t,N} \, ds < \infty \text{ a.s.}
\]

(i) \( \sup_{r \leq t; |h| \leq N} \left( |U_s(h, r)| + \sum_{i=1}^k \left[ |\partial V_i^i(h, r)| + |V_s^i(h, r)|^2 \right] \right) \leq \alpha_t^{t,N}, 0 \leq s \leq t \)

\( \forall (\omega, t) \in \Omega \times \mathbb{R}_+, \)

(HA.2) \( (h, r) \rightarrow (U_t(h, r), V_t^1(h, r), \ldots, V_t^k(h, r), \partial V_t^1(h, r), \ldots, \partial V_t^k(h, r)) \)

is continuous.

We assume moreover that:

(HA.3) \( \forall (\omega, t) \in \Omega \times \mathbb{R}_+, (h, r) \rightarrow T_t(h, r) \) is of class \( C^{2,1} \), and \( \forall \omega \in \Omega, T, \frac{\partial T}{\partial h}, \frac{\partial^2 T}{\partial h^2}, \frac{\partial T}{\partial r} \) are locally bounded in \((t, h, r)\).

Let \( \{H_t\} \) be a p-dimensional semi-martingale which satisfies (H.14) and (H.15). Then the following holds:

\[
T_t(H_t, t) = T_0(H_0, 0) + \int_0^t U_s(H_s, s) \, ds + \int_0^t V_s^i(H_s, s) \, dW^i_s
\]

(A.2) \( + \int_0^t \frac{\partial T_s^i}{\partial h}(H_s, s)K_s \, ds + \int_0^t \frac{\partial T_s^i}{\partial r}(H_s, s) \, ds + \int_0^t \frac{\partial T_s^i}{\partial h}(H_s, s)L_s^i \, dW^i_s
\]

\( + \int_0^t \frac{1}{2} \int_0^t \frac{\partial^2 T_s^i}{\partial h^2}(H_s, s)L_s^i, L_s^i > ds + \int_0^t \frac{\partial V_s^i}{\partial h}(H_s, s)L_s^i \, ds \)

**Proof:** Note that each term in (A.1) is \( \mathcal{P} \otimes B^+_p \) measurable, where \( B^+_p \) denotes the Borel field over \( \mathbb{R}^p \times R_+ \). By using a classical localization procedure, it suffices to prove
the result in the case where $H_t, T_t(h, r), \frac{\partial T_t}{\partial h}(h, r), \frac{\partial^2 T_t}{\partial h^2}(h, r)$ and $\int_0^t \alpha_s^i \, ds$ are uniformly bounded by a constant $c$ which is independent of $\omega, t, h$ and $r$. Therefore we make these assumptions w.l.o.g.

We extend below any function which was defined on $\mathcal{R}_+$ as a function defined on $\mathcal{R}$ by taking it to be zero on $\mathcal{R}_-$. Let $\varphi \in C_c^\infty(\mathcal{R}^p), \psi \in C_c^\infty(\mathcal{R})$. From Itô's formula,

\[
\varphi(h - H_t)\psi(r - t) = \varphi(h - H_0)\psi(r) - \int_0^t \varphi'(h - H_s)K_s\psi(r - s) \, ds
\]

\[
- \int_0^t \varphi(h - H_s)\psi'(r - s) \, ds - \int_0^t \varphi'(h - H_s)L_s^i\psi(r - s) \, dW_s^i
\]

\[
+ \frac{1}{2} \int_0^t <\varphi''(h - H_s)L_s^i,L_s^i> \psi(r - s) \, ds,
\]

and also:

\[
T_t(h, r)\varphi(h - H_t)\psi(r - t) = T_0(h, r)\varphi(h - H_0)\psi(r) + \int_0^t U_s(h, r)\varphi(h - H_s)\psi(r - s) \, ds
\]

\[
+ \int_0^t V_s^i(h, r)\varphi(h - H_s)\psi(r - s) \, dW_s^i - \int_0^t T_s(h, r)\varphi'(h - H_s)K_s\psi(r - s) \, ds
\]

\[
- \int_0^t T_s(h, r)\varphi(h - H_s)\psi'(r - s) \, ds - \int_0^t T_s(h, r)\varphi'(h - H_s)L_s^i\psi(r - s) \, dW_s^i
\]

\[
+ \frac{1}{2} \int_0^t T_s(h, r) <\varphi''(h - H_s)L_s^i,L_s^i> \psi(r - s) \, ds
\]

\[
- \int_0^t V_s^i(h, r)\varphi'(h - H_s)L_s^i\psi(r - s) \, ds.
\]

We integrate the above identity with respect to $dh \, dr$ over $\mathcal{R}^p \times \mathcal{R}$, and interchange the $dh \, dr$ and the $ds$ (resp. the $dW_s^i$) integrals, using Fubini's theorem (resp. Theorem 5.44 in Jacod [5]). We moreover integrate by parts all integrals involving derivatives of $\varphi$, 

20
\[ \int_{R^p \times R} T_t(h, r) \varphi(h - H_t) \psi(r - t) \, dh \, dr = \int_{R^p \times R} T_0(h, r) \varphi(h - H_0) \psi(r - 0) \, dh \, dr \\
+ \int_0^t ds \int_{R^p \times R} U_s(h, r) \varphi(h - H_s) \psi(r - s) \, dh \, dr \\
+ \int_0^t dW_s^i \int_{R^p \times R} V_s^i(h, r) \varphi(h - H_s) \psi(r - s) \, dh \, dr \\
- \int_0^t ds \int_{R^p \times R} \frac{\partial T_s}{\partial h}(h, r) \varphi(h - H_s) K_s \psi(r - s) \, dh \, dr \\
+ \int_0^t ds \int_{R^p \times R} \frac{\partial T_s}{\partial r}(h, r) \varphi(h - H_s) \psi(r - s) \, dh \, dr \\
+ \int_0^t dW^i_s \int_{R^p \times R} \frac{\partial T_s}{\partial h}(h, r) \varphi(h - H_s) L^i_s \psi(r - s) \, dh \, dr \\
+ \frac{1}{2} \int_0^t ds \int_{R^p \times R} < \frac{\partial^2 T_s}{\partial h^2}(h, r) L^i_s, L^i_s > \varphi(h - H_s) \psi(r - s) \, dh \, dr \\
- \int_0^t ds \int_{R^p \times R} \frac{\partial V_s^i}{\partial h}(h, r) \varphi(h - H_s) L^i_s \psi(r - s) \, dh \, dr. \]

It remains to replace \( \varphi \) and \( \psi \) by sequences \( \{\varphi_n\} \) and \( \{\psi_n\} \) which converge to the Dirac measure at 0, as \( n \to \infty \), and let \( n \to \infty \). The convergence follows easily from our hypotheses. \( \square \)
