### **ABSTRACT**

In the problem of selecting the best of k populations, a natural rule is to select the population corresponding to the largest sample value of an appropriate statistic. As a retrospective analysis, a lower confidence bound on the probability of a correct selection is derived when the probability density function has the monotone likelihood ratio property under the location parameter setting. The result is applied to the normal populations with both known and unknown common variance. Tables to implement the confidence bound are provided.

KEY WORDS: Selection problem; A retrospective analysis; Probability of a correct selection; Lower confidence bound; Monotone likelihood ratio.

# A Lower Confidence Bound on the Probability of a Correct Selection

### INTRODUCTION

Consider independent observations  $X_{ij}$  from each of  $k_i$  populations with cdf's  $G(x-\theta_i)$ ,  $i=1,2,\ldots,k$ ,  $j=1,2,\ldots,n$ . The experimenter wishes to select the "best" population associated with the largest parameter  $\theta_i$ . For this purpose, we choose an appropriate statistic  $Y_i=Y(X_{i1},\ldots,X_{in})$  with cdf  $F_n(y-\theta_i)$  and use the natural selection rule which selects the population corresponding to the largest  $Y_i$  as the best.

For this selection problem, Bechhofer (1954) introduced the indifference zone approach in which we determine the sample size n, prior to the experiment, to control the probability of a correct selection (PCS)

$$PCS = \int_{-\infty}^{\infty} \prod_{i=1}^{\pi} F_{\mathbf{n}}(Y + \theta_{[k]} - \theta_{[i]}) d F_{\mathbf{n}}(y)$$
(1.1)

where  $\theta_{[1]} \leq \theta_{[2]} \leq \cdots \leq \theta_{[k]}$  are the ordered parameters. In controlling the PCS, we need to specify a preference zone where the largest two parameters  $\theta_{[k]}$  and  $\theta_{[k-1]}$  are far apart. This indifference zone approach is clearly formulated from the point of view of designing experiment.

Recently retrospective analyses regarding the PCS have been studied by Gibbons, Olkin, and Sobel (1977), Anderson, Bishop, and Dudewicz (1977),

Olkin, Sobel, and Tong (1982), and Faltin and McCulloch (1983) among others. Most of these studies have dealt with the point estimation of the PCS.

Gibbons, Olkin, and Sobel (1977) and Olkin, Sobel, and Tong (1982) have presented interval estimates of PCS. However the coverage probabilities of such interval estimates have not be discussed. Thus they can not be interpreted as confidence interval estimates (see Bechhofer 1980, p. 753). In the case of normal populations, Anderson, Bishop, and Dudewicz (1977) have given a lower confidence bound on PCS. The quantile unbiased estimator in Faltin (1980) can also be regarded as a lower confidence bound on PCS. However, it is restricted to the special case of k=2 populations.

This article presents a lower confidence bound on PCS when the pdf  $f_n(y-\theta)$  of  $F_n(y-\theta)$  has the monotone likelihood ratio (MLR) in y and  $\theta$ . From this result, we obtain a lower confidence bound on PCS in the case of normal populations with both known and unknown common variance. The obtained lower confidence bound is sharper than that of Anderson, Bishop, and Dudewicz (1977), and reduces to that of Faltin (1980) in the special case of k=2 populations. Tables to implement the lower confidence bound as well as an illustrative example are given.

### 2. A LOWER CONFIDENCE BOUND ON PCS

It can be easily seen from the inquality

$$PCS \ge \int_{-\infty}^{\infty} F^{k-1}(y + \theta_{\lfloor k \rfloor} - \theta_{\lfloor k-1 \rfloor}) d F(y)$$
 (2.1)

that a (conservative) lower confidence bound on PCS can be obtained from a lower confidence bound on  $\theta_{[k]} - \theta_{[k-1]}$ . Thus we begin with constructing a

lower confidence bound on  $\theta[k]^{-\theta}[k-1]$ . To do this, let  $Y(1) \leq Y(2) \leq \cdots \leq Y(k)$  denote the ordered statistics of  $Y_1, Y_2, \ldots, Y_k$ , and let f(y) denote the pdf of F. Note that the dependence of F and f on n is suppressed notationally.

We first state a lemma which is a generalization of a result in Anderson, Bishop, and Dudewicz (1977).

<u>Lemma 1</u>. Assume that log f(y) is concave. Then for any fixed c>0,  $P_{\theta}[Y_{(k)}-Y_{(k-1)})>c] \text{ is non-increasing in } \theta_{[1]}.$ 

<u>Proof.</u> By semmetry we may assume  $\theta_1 \leq ... \leq \theta_k$ . Then, for any c>0, we have

$$P_{\ell}[Y_{(k)}-Y_{(k-1)}>c] = \sum_{j=1}^{k} \int_{-\infty}^{\infty} \prod_{\substack{i=1\\i\neq j}}^{k} F(y+\theta_{j}-\theta_{i}-c) f(y) dy.$$

Therefore,

$$\begin{split} &\frac{\partial}{\partial \theta_{1}} P_{\theta}^{[Y}(k)^{-Y}(k-1)^{>c}] \\ &= \sum_{j=2}^{k} \int_{-\infty}^{\infty} \prod_{\substack{i=2\\i\neq j}}^{k} F(y+\theta_{1}-\theta_{i}-c) f(y+\theta_{1}-\theta_{j}-c) f(y) dy - \\ &\sum_{j=2}^{k} \int_{-\infty}^{\infty} \prod_{\substack{i=2\\i\neq j}}^{k} F(y+\theta_{j}-\theta_{i}-c) f(y+\theta_{j}-\theta_{1}-c) f(y) dy \\ &= \sum_{j=2}^{k} \int_{-\infty}^{\infty} \prod_{\substack{i=2\\i\neq j}}^{k} F(y-\theta_{i}-c) [f(y-\theta_{j}-c) f(y-\theta_{1}) - f(y-\theta_{1}-c) f(y-\theta_{j})] dy. \end{split}$$

By the equivalence between the assumption and the MLR of  $f(y-\theta)$  in y and  $\theta$ , the expression in the brackets is non-positive. Hence the result follows.

To define a lower confidence bound, let

$$H(x) = \int_{-\infty}^{\infty} F(x+y) f(y) dy$$

denote the cdf of  $(Y_1-\theta_1)$  -  $(Y_2-\theta_2)$  and let  $x_{\alpha/2}$  denote the upper  $\alpha/2$  quantile of H(x) for  $0<\alpha<1$ . Note that H(x) is symmetric and  $x_{\alpha/2}>0$ . For a given  $0<\alpha<1$  and for  $t \geq x_{\alpha/2}$ , we define a non-negative function  $L_{\alpha}(t) = L(t)$  by

$$H(L(t)-t) + H(-L(t)-t) = \alpha.$$
 (2.2)

The existence of such a function L(t) for  $t \ge x_{\alpha/2}$  is proved in the Appendix under the assumption in Lemma 1. Also it can be easily observed that the function L(t) is strictly increasing for  $t \ge x_{\alpha/2}$ .

We present an exact  $100(1-\alpha)\%$  lower confidence bound on  $\theta_{\lfloor k \rfloor} - \theta_{\lfloor k-1 \rfloor}$  in the following theorem.

Theorem 1. Assume that log f(y) is concave. Then

$$\inf_{\theta} P_{\theta} [\theta[k]^{-\theta}[k-1] \ge L(Y(k)^{-Y}(k-1))] = 1-\alpha$$
 (2.3)

where L(t) is defined by (2.2) for  $t \ge x_{\alpha/2}$  and 0 for  $0 \le t \le x_{\alpha/2}$ .

<u>Proof.</u> For any fixed  $\theta_{[k]}$  and  $\theta_{[k-1]}$ , let  $\Delta = \theta_{[k]} - \theta_{[k-1]}$ . Then it follows from Lemma 1 that for all  $\theta$ 

$$P_{\theta}^{[\Delta]} \geq L(Y(k)^{-Y}(k-1)^{)}$$

$$= P_{\theta}^{[L^{-1}(\Delta)]} \geq Y(k)^{-Y}(k-1)^{]}$$

$$\geq P_{\theta}^{[L^{-1}(\Delta)]} \geq |Y_{[k]}^{-Y}[k-1]^{]}$$

where  $L^{-1}(0)$  is taken as  $x_{\alpha/2}$ . Note that the equality can be attained when  $\theta_{[1]} = \theta_{[2]} = \dots = \theta_{[k-2]} = -\infty$ . Furthermore, for any value of  $\Delta$ , we have

$$P_{\theta}[L^{-1}(\Delta) \ge |Y_{[k]}^{-1}|]$$
= 1 - {H(\Delta - 1(\Delta)) + H(-\Delta - 1(\Delta))}
= 1 - \alpha

which completes the proof.

A simple but useful corollary to Theorem 1 is the following.

Corollary 1. Under the assumption of Theorem 1, we have

$$P_{\theta}[PCS \ge \hat{P}_L] \ge 1 - \alpha$$
 for all  $\theta$ 

where

$$\hat{P}_{L} = \int_{-\infty}^{\infty} F^{k-1}(y+L(Y_{(k)}-Y_{(k-1)})) d F(y).$$
 (2.4)

The lower confidence bounds in (2.3) and (2.4) become trivial when  ${}^{Y}(k)^{-Y}(k-1) \leq x_{\alpha/2}, \text{ that is, when the data do not show significant evidence} \\ \text{for } {}^{\theta}_{\lfloor k \rfloor} > {}^{\theta}_{\lfloor k-1 \rfloor}. \text{ In fact, it can be easily shown that any lower confidence} \\ \text{bound for } {}^{\theta}_{\lfloor k \rfloor} {}^{-\theta}_{\lfloor k-1 \rfloor}, \text{ which is a non-negative and non-decreasing function} \\ \text{of } {}^{Y}(k)^{-Y}(k-1), \text{ becomes trivial in such a case.}$ 

### 3. NORMAL POPULATIONS WITH A COMMON VARIANCE

Let  $X_{i,j}$  be independent observations from  $N(\mu_i, \sigma^2)$ ,  $i=1, \ldots, k$ ,  $j=1, \ldots, n$ , where the common variance  $\sigma^2 > 0$  may be either known or unknown. The best population is the one associated with  $\mu_{\lfloor k \rfloor} = \max_{\substack{1 \leq i \leq k \\ \text{population corresponding to the largest sample mean } \overline{X}_i$  as the best. The probability of a correct selection is

$$PCS = \int_{-\infty}^{\infty} \prod_{i=1}^{\pi} \Phi(x + \sqrt{n}(\mu_{k})^{-\mu_{i}})/\sigma) d\Phi(x)$$
(3.1)

where  $\mu_{\lceil 1 \rceil} \leq \cdots \leq \mu_{\lceil k \rceil}$  are the ordered  $\mu_i$ 's and  $\Phi$  is the standard normal cdf.

In the case of known variance, by taking  $Y_i = \sqrt{n} \ \overline{X}_i / \sigma$  and  $\theta_i = \sqrt{n} \ \mu_i / \sigma$  in Theorem 1 and Corollary 1, we can make the following statement with 100  $(1-\alpha)$ % confidence;

$$(\mu_{\lfloor k \rfloor}^{-\mu} \lfloor k-1 \rfloor) / \sigma \geq \sqrt{2/n} \ h(\sqrt{n} \ (\overline{X}_{(k)}^{-\overline{X}} (k-1)) / \sqrt{2} \ \sigma)$$

$$PCS \geq \int_{-\infty}^{\infty} \Phi^{k-1} \left[ x + \sqrt{2}h(\sqrt{n}(\overline{X}_{(k)}^{-\overline{X}} (k-1)) / \sqrt{2} \ \sigma) \right] d \Phi(x)$$

$$(3.2)$$

where  $\overline{X}_{(1)} \leq \cdots \leq \overline{X}_{(k)}$  are the ordered sample means and the non-negative function h(t) is defined by

$$\Phi(h(t)-t) + \Phi(-h(t)-t) = \alpha$$
 (3.3)

for  $t \ge z_{\alpha/2}$  and h(t) = 0 for  $0 \le t \le z_{\alpha/2}$ . Here,  $z_{\alpha/2}$  is the upper  $\alpha/2$  quantile of the standard normal distribution.

When the common variance  $\sigma^2$  is unknown, let  $S^2$  denote the pooled sample variance. Note that  $\nu S^2/\sigma^2$  has a  $\chi^2$  distribution with  $\nu = k(n-1)$  degrees of freedom. Since  $S^2$  is independent of  $\overline{\chi}_1,\ldots,\overline{\chi}_k$ , this case can be treated similarly by considering the conditional coverage probability given  $S^2 = s^2$  and by taking  $Y_i = \sqrt{n} \ \overline{\chi}_i/\sigma$ ,  $\theta_i = \sqrt{n} \ \mu_i/\sigma$ . Therefore we omit the derivation for the following confidence statement; With 100  $(1-\alpha)\%$  confidence, we have

$$(\mu_{\lceil k \rceil}^{-\mu} [k-1])/\sigma \geq \sqrt{2/n} h_{\chi} (\sqrt{n} (\overline{\chi}_{(k)}^{-\overline{\chi}} (k-1))/\sqrt{2} s)$$

$$PCS \geq \int_{-\infty}^{\infty} \Phi^{k-1} \left[ x + \sqrt{2} h_{v} \left( \sqrt{n} \left( \overline{X}_{(k)} - \overline{X}_{(k-1)} \right) \right) / \sqrt{2} S \right) \right] d \Phi(x)$$
 (3.4)

where the non-negative function  $h_{y}(t)$  is given by

$$\int_0^\infty \left[ \Phi(h_v(t) - tu) + \Phi(-h_v(t) - tu) \right] dQ_v(u) = \alpha$$
 (3.5)

for  $t \ge t_{\alpha/2}(v)$  and  $h_v(t) = 0$  for  $0 \le t \le t_{\alpha/2}(v)$ . Here,  $t_{\alpha/2}(v)$  is the upper  $\alpha/2$  quantile of the t-distribution with v degrees of freedom and  $Q_v(u)$  is the cdf of  $\chi/\sqrt{v}$ .

The values of the function  $h_{\nu}(t)$  are given in Tables 1 and 2 for  $\alpha$  = 0.05, 0.10 and for selected values of  $\nu$  and  $t \geq t_{\alpha/2}(\nu)$ . Note that  $h_{\nu}(t) = h(t)$  for  $\nu=\infty$ . Details of the computational techniques are given in the Appendix. As can be seen from Figure 1, our computations have indicated that the function

 $h_{\nu}(t)$  becomes nearly linear for moderately large values of  $t-t_{\alpha/2}(\nu)$ . For t values larger than those in Tables 1 and 2, the values of  $h_{\nu}(t)$  satisfying (3.5) can be found numerically or be approximated by linear extrapolation. Especially in the case of known variance  $(\nu=\infty)$ , it can be easily shown that

It follows from the lower bound on h(t) in (3.6) that the lower confidence bound in (3.2) is sharper than the one in Anderson, Bishop, and Dudewicz (1977). It can also be easily observed that in the special case of k=2 it reduces to the one in Faltin (1980).

## Tables 1 and 2 approximately here

### 4. AN EXAMPLE

For illustration purpose, we consider an example given by Kleijnen, Naylor, and Seaks (1972), in which a firm that produces a single product from a multistage production process is interested in selecting the one most profitable production plan among k=5 possible plans. They run simulation experiments with a sample of size n=50 for each plan and assume that the profit using each plan has a normal distribution with a common unknown variance. The data are as follows:

Plan i	Mean profit	Standard deviation
1	2976.40	175.83
2	2992.30	202.20
3	2675.20	250.51
4	3265.30	221.81
5	3131.90	277.04

From the given data, plan 4 yields the largest sample mean and is selected as the most-profitable plan. A reasonable question is: what kind of confidence statement can be made regarding the PCS? First, we observe that the pooled sample standard deviation is s = 228.26 with v = 5(49) = 245 degrees of freedom and  $t = \sqrt{n} \left( \overline{x}_{(5)} - \overline{x}_{(4)} \right) / \sqrt{2} s = 2.92$ . Choosing  $\alpha = .10$ , we find  $\sqrt{2} h_v(t) = 2.32$  by (3.6). Using Table A.2 in Gibbons, Olkin, and Sobel (1977) for the integral value in (3.4), we can state with 90% confidence that PCS  $\geq .856$ .

### CONCLUDING REMARKS

The results in Section 2 are derived for location parameter families. However, similar results for scale parameter families can be obtained. For the problem of selecting the population with the largest scale parameter  $\theta_1$ , the PCS in (1.1) is replaced by

$$PCS = \int_0^\infty \prod_{i=1}^{K-1} F(\theta_{[k]} y/\theta_{[i]}) d F(y)$$
(5.1)

where  $F(y/\theta_i)$  is the cdf of an appropriate statistic  $Y_i \ge 0$ . Similar analysis yields, under the assumption of MLR of the pdf  $\frac{1}{\theta}$  f( $\frac{y}{\theta}$ ) in y and  $\theta$ , that the  $100(1-\alpha)\%$  lower confidence bound in (2.4) can be replaced by

$$\hat{P}_{L} = \int_{0}^{\infty} F^{k-1}(y L(Y_{(k)}/Y_{(k-1)})) d F(y).$$
 (5.2)

The function L(t) in (5.2) is defined by

$$H(L(t)/t) + H((tL(t))^{-1}) = \alpha$$

for  $t \ge x_{\alpha/2}$  and  $L_{(t)} = 1$  for  $0 < t < x_{\alpha/2}$  where H(x) is the cdf of  $Y_1/Y_2$  for  $\theta_1 = \theta_2$  and  $x_{\alpha/2}$  is the upper  $\alpha/2$  quantile of H(x). Also, obvious modifications can be made for the problem of selecting the population with the smallest scale parameter. Such modifications can be useful, for example, for the normal variances problem.

As a final remark, we point out that the lower confidence bound in (2.4) is conservative due to the use of the inequality (2.1). To obtain an exact lower confidence bound on PCS, one needs a simultaneous lower confidence bounds on  $\theta_{\lceil k \rceil} = \theta_{\lceil i \rceil}$ ,  $i=1,2,\ldots,k-1$  which the author was unable to obtain.

### **APPENDIX**

To show the existence of a non-negative function L(t) satisfying (2.2), we assume that log f(y) is concave and let  $\Psi_{\mathbf{t}}(a) = H(a-t) + H(-a-t)$  for fixed  $t \ge x_{\alpha/2}$ . Then

$$\frac{d}{da} \Psi_{t}(a) = H'(a-t) - H'(a+t)$$

$$= \int_{-\infty}^{\infty} [f(y-t)-f(y+t)] f(y-a)dy \qquad (A.1)$$

where H'(x) is the pdf of H(x).

Note that the expression in the brackets in (A.1) changes sign once from - to + as y varies from - $\infty$  to + $\infty$ . Therefore, by the sign diminishing property of MLR (see, for example, Lehmann 1954, p. 74),  $\frac{d}{da} \Psi_t(a)$  changes sign at most

once from - to + as a varies from  $-\infty$  to  $+\infty$ . Furthermore, by the symmetry of H'(t),  $\frac{d}{da} \Psi_{t}(a) = 0$  for a = 0. Thus  $\Psi_{t}(a)$  is strictly increasing in  $a \geq 0$ . Also it can be observed that for fixed  $t \geq x_{\alpha/2}$ ,  $\Psi_{t}(0) = 2H(-t) \leq \alpha$  and  $\Psi_{t}(a) \rightarrow 1$  as  $a \rightarrow \infty$ . Hence L(t) can be defined by (2.2).

For constructing Tables 1 and 2, numerical evaluation of the integral in (3.5) was done via IMSL's subroutine MDTN. In the case of a known variance  $(v=\infty)$ , MDNOR was used. The value of  $h_v(t)$  was found numerically by finding a root of (3.3) or (3.5) via the modified regula falsi method with the accuracy up to  $10^{-5}$ . Then, the values of  $h_v(t)$  were rounded.
